Package ‘dclone’

February 19, 2015

Type Package

Title Data Cloning and MCMC Tools for Maximum Likelihood Methods

Version 2.0-0

Date 2013-09-27

Author Peter Solymos

Maintainer Peter Solymos <solymos@ualberta.ca>

Description Low level functions for implementing
maximum likelihood estimating procedures for
complex models using data cloning and Bayesian
Markov chain Monte Carlo methods.
Sequential and parallel MCMC support
for JAGS, WinBUGS and OpenBUGS.

License GPL-2

Depends R (>= 2.15.1), coda (>= 0.13), parallel

Suggests MASS, lattice, rjags (>= 3-5), R2WinBUGS, R2OpenBUGS, BRugs,
snow, rlecuyer

Imports stats

SystemRequirements none, one or more of JAGS (>= 3.0.0), WinBUGS (>=
1.4), OpenBUGS (>= 3.2.2)

Description

Low level functions for implementing maximum likelihood estimating procedures for complex models using data cloning and Bayesian Markov chain Monte Carlo methods. Sequential and parallel MCMC support for JAGS, WinBUGS and OpenBUGS.

Main functions include:

- `dclone, dcdim, dciid, dct`: cloning R objects in various ways.
- `jags.fit, bugs.fit`: conveniently fit BUGS models. `jags.parfit` and `bugs.parfit` fits chains on parallel workers.
- `dc.fit`: iterative model fitting by the data cloning algorithm. `dc.parfit` is the parallelized version.
- `dctable, dcdiag`: helps evaluating data cloning convergence by descriptive statistics and diagnostic tools. (These are based on e.g. `chisq.diag` and `lambdamax.diag`.)
- `coef.mcmc.list.confint.mcmc.list, dc.mcmc.list, quantile.mcmc.list, vcov.mcmc.list, ddc.mcmc.list, mcmcapply, stack.mcmc.list`: methods for `mcmc.list` objects.
- `write.jags.model, clean.jags.model, custommodel`: convenient functions for handling BUGS models.
- `jagsModel, codaSamples`: basic functions from `rjags` package rewrote to recognize data cloning attributes from data (`parJagsModel, parUpdate, parCodaSamples` are the parallel versions).

Internal function for iterative model fitting with data cloning

Description

This is the workhorse for dc.fit and dc.parfit.

Usage

`.dcFit`(data, params, model, inits, n.clones, multiply = NULL, unchanged = NULL, update = NULL, updatefun = NULL, initsfun = NULL, flavour = c("jags", "bugs"), n.chains=3, cl = NULL, parchains = FALSE, ...)

Arguments

data: A named list (or environment) containing the data.
params: Character vector of parameters to be sampled. It can be a list of 2 vectors, 1st element is used as parameters to monitor, the 2nd is used as parameters to use in calculating the data cloning diagnostics.
model: Character string (name of the model file), a function containing the model, or a `custommodel` object (see Examples).
inits: Optional specification of initial values in the form of a list or a function (see Initialization at `jags.model`). If missing, will be treated as NULL and initial values will be generated automatically.
n.clones: An integer vector containing the numbers of clones to use iteratively.
multiply: Numeric or character index for list element(s) in the data argument to be multiplied by the number of clones instead of repetitions.
unchanged: Numeric or character index for list element(s) in the data argument to be left unchanged.
update: Numeric or character index for list element(s) in the data argument that has to be updated by updatefun in each iterations. This usually is for making priors more informative, and enhancing convergence. See Details and Examples.
updatefun: A function to use for updating data[[update]]. It should take an `mcmc.list` object as 1st argument, 2nd argument can be the number of clones. See Details and Examples.
initsfun: A function to use for generating initial values, inits are updated by the object returned by this function from the second iteration. If initial values are not dependent on the previous iteration, this should be NULL, otherwise, it should take an `mcmc.list` object as 1st argument, 2nd argument can be the number of clones. This feature is useful if latent nodes are provided in inits so it also requires to be cloned for subsequent iterations. See Details and Examples.
flavour: If "jags", the function `jags.fit` is called. If "bugs", the function `bugs.fit` is called.
n.chains: Number of chains to generate.
cl: A cluster object created by `makeCluster`, or an integer, see `parDosa` and `evalParallelArgument`.
parchains: Logical, whether parallel chains should be run.
...: Other values supplied to `jags.fit`, or `bugs.fit`, depending on the `flavour` argument.

Value
An object inheriting from the class 'mcmc.list'.

Author(s)
Peter Solymos, <solymos@ualberta.ca>, implementation is based on many discussions with Khurram Nadeem and Subhash Lele.

**bugs.fit**

Fit BUGS models with cloned data

Description
Convenient functions designed to work well with cloned data arguments and WinBUGS and OpenBUGS.

Usage

```r
bugs.fit(data, params, model, inits = NULL, n.chains = 3,
  format = c("mcmc.list", "bugs"),
  program = c("winbugs", "openbugs", "brugs"),
  seed, ...)
```

## S3 method for class 'bugs'
as.mcmc.list(x, ...)

Arguments

- **data**: A list (or environment) containing the data.
- **params**: Character vector of parameters to be sampled.
- **model**: Character string (name of the model file), a function containing the model, or a `custommodel` object (see Examples).
- **inits**: Optional specification of initial values in the form of a list or a function. If `NULL`, initial values will be generated automatically.
n.chains  number of Markov chains.
format  Required output format.
program  The program to use, not case sensitive. winbugs calls the function bugs from package R2WinBUGS, openbugs calls the function bugs from package R2OpenBUGS (this has changed since delone version 1.8-1, this is now the preferred OpenBUGS interface). bugs calls the function openbugs from package R2WinBUGS and requires the CRAN package BRugs (this is provided for back compatibility purposes, but gives a warning because it is not the preferred interface to R2OpenBUGS).
seed  Random seed (bugs.seed argument for bugs in package R2WinBUGS or bugs in package R2OpenBUGS, seed argument for openbugs). It takes the corresponding default values (NULL or 1) when missing.
x  A fitted 'bugs' object.
...  Further arguments of the bugs function, except for codapkg are passed also, most notably the ones to set up burn-in, thin, etc. (see Details).

Value

By default, an mcmc.list object. If data cloning is used via the data argument, summary returns a modified summary containing scaled data cloning standard errors (scaled by sqrt(n.clones)), and $R_{hat}$ values (as returned by gelman.diag).
bugs.fit can return a bugs object if format = "bugs". In this case, summary is not changed, but the number of clones used is attached as attribute and can be retrieved by the function nclones.
The function as.mcmc.list.bugs converts a 'bugs' object into 'mcmc.list' and retrieves data cloning information as well.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

  summary(sim4)
}
if (require(rjags)) {
  ## fitting the model with JAGS
  sim5 <- jags.fit(dat2, param, bugs.model)
  summary(sim5)
}

## End(Not run)
Description

Does the same job as `bugs.fit`, but parallel chains are run on parallel workers, thus computations can be faster (up to \(1/n\).chains) for long MCMC runs.

Usage

```r
bugs.parfit(cl, data, params, model, inits=NULL, n.chains = 3,
            seed, program=c("winbugs", "openbugs", "brugs"), ...)
```

Arguments

- `cl` A cluster object created by `makeCluster`, or an integer, see `parDosa` and `evalParallelArgument`.
- `data` A named list or environment containing the data. If an environment, `data` is coerced into a list.
- `params` Character vector of parameters to be sampled.
- `model` Character string (name of the model file), a function containing the model, or a `customModel` object (see Examples).
- `inits` Specification of initial values in the form of a list or a function, can be missing. If this is a function and using 'snow' type cluster as `cl`, the function must be self containing, i.e. not having references to R objects outside of the function, or the objects should be exported with `clusterExport` before calling `bugs.parfit`. Forking type parallelism does not require such attention.
- `n.chains` Number of chains to generate, must be higher than 1. Ideally, this is equal to the number of parallel workers in the cluster.
- `seed` Vector of random seeds, must have `n.chains` unique values. See Details.
- `program` The program to use, not case sensitive. See `bugs.fit`.
- `...` Other arguments passed to `bugs.fit`.

Details

Chains are run on parallel workers, and the results are combined in the end.

The seed must be supplied, as it is the user’s responsibility to make sure that pseudo random sequences do not seriously overlap.

The WinBUGS implementation is quite unsafe from this regard, because the pseudo-random number generator used by WinBUGS generates a finite (albeit very long) sequence of distinct numbers, which would eventually be repeated if the sampler were run for a sufficiently long time. Thus it’s usage must be discouraged. That is the reason for the warning that is issued when `program = "winbugs"`.

OpenBUGS (starting from version 3.2.2) implemented a system where internal state of the pseudo random number generator can be set to one of 14 predefined states (seed values in 1:14). Each predefined state is \(10^{12}\) draws apart to avoid overlap in pseudo random number sequences.

Value

An `mcmc.list` object.

  }
}
```
clusterSize

### Optimizing the number of workers

#### Description
These functions help in optimizing workload for the workers if problems are of different size.

#### Usage
```r
clusterSize(size)
plotClusterSize(n, size,
  balancing = c("none", "load", "size", "both"),
  plot = TRUE, col = NA, xlim = NULL, ylim = NULL,
  main, ...)
```

#### Arguments
- `n` Number of workers.
- `size` Vector of problem sizes (recycled if needed). The default `1` indicates equality of problem sizes.
- `balancing` Character, type of balancing to perform, one of `c("none", "load", "size", "both")`.
- `plot` Logical, if a plot should be drawn.
- `col` Color of the polygons for work load pieces.
- `xlim, ylim` Limits for the x and the y axis, respectively (optional).
- `main` Title of the plot, can be missing.
- `...` Other arguments passed to `polygon`.

#### Details
These functions help determine the optimal number of workers needed for different sized problems ('size' indicates approximate processing time here). The number of workers needed depends on the type of balancing.

For the description of the balancing types, see `snowWrapper`.

```r
summary(sim4)
}
stopCluster(cl)
## multicore type forking
if (require(R2OpenBUGS) && .Platform$OS.type != "windows") {
sim7 <- bugs.parfit(3, dat2, param, bugs.model,
  program="openbugs", n.iter=2000, n.thin=1, seed=1:3)
summary(sim7)
}
## End(Not run)
```
clusterSplitSB

Value

clusterSize returns a data frame with approximate processing time as the function of the number of workers (rows, in 1:length(size)) and the type of balancing (c("none", "load", "size", "both")). Approximate processing time is calculated from values in size without taking into account any communication overhead.

plotClusterSize invisibly returns the total processing time needed for a setting given its arguments. As a side effect, a plot is produced (if plot = TRUE).

Author(s)

Peter Solymos, <solymos@ualberta.ca>

Examples

## determine the number of workers needed
cclusterSize(1:5)
## visually compare balancing options
opar <- par(mfrow=c(2, 2))
plotClusterSize(2:1:5, "none")
plotClusterSize(2:1:5, "load")
plotClusterSize(2:1:5, "size")
plotClusterSize(2:1:5, "both")
par(opar)

Description

Functions for size balancing.

Usage

clusterSplitSB(cl, seq, size = 1)
parLapplySB(cl, x, size = 1, fun, ...)
parLapplySLB(cl, x, size = 1, fun, ...)

Arguments

cl A cluster object created by makeCluster the the package parallel (or snow).
x, seq A vector to split.
fun A function or character string naming a function.
size Vector of problem sizes (approximate processing times) corresponding to elements of seq (recycled if needed). The default 1 indicates equality of problem sizes.
... Other arguments of fun.
Details

`clusterSplitSB` splits seq into subsets, with respect to size. In size balancing, the problem is re-ordered from largest to smallest, and then subsets are determined by minimizing the total approximate processing time. This splitting is deterministic (reproducible).

`parLapplySB` and `parLapplySLB` evaluates `fun` on elements of `x` in parallel, similarly to `parLapply`. `parLapplySB` uses size balancing (via `clusterSplitSB`), `parLapplySLB` uses size and load balancing. This means that the problem is re-ordered from largest to smallest, and then undeterministic load balancing is used (see `clusterApplyLB`). If size is correct, this is identical to size balancing. This splitting is non-deterministic (might not be reproducible).

Value

`clusterSplitSB` returns a list of subsets splitted with respect to size.

`parLapplySB` and `parLapplySLB` evaluates `fun` on elements of `x`, and return a result corresponding to `x`. Usually a list with results returned by the cluster.

Related functions without size balancing: `clusterSplit, parLapply`.

Underlying functions: `clusterApply, clusterApplyLB`.

Optimizing the number of workers: `clusterSize, plotClusterSize`.

Examples

```r
## Not run:
c1 <- makePSOCKcluster(2)
## equal sizes, same as clusterSplit(c1, 1:5)
clusterSplitSB(c1, 1:5)
## different sizes
clusterSplitSB(c1, 1:5, 5:1)
x <- list(1, 2, 3, 4)
parLapplySB(c1, x, function(z) z^2, size=1:4)
stopCluster(c1)

## End(Not run)
```
codaSamples Generate posterior samples in mcmc.list format

Description

This function sets a trace monitor for all requested nodes, updates the model and coerces the output to a single mcmc.list object. This function uses coda.samples but keeps track of data cloning information supplied via the model argument.

Usage

codaSamples(model, variable.names, n.iter, thin = 1, ...)

Arguments

model a jags model object
variable.names a character vector giving the names of variables to be monitored
n.iter number of iterations to monitor
thin thinning interval for monitors
... optional arguments that are passed to the update method for jags model objects

Value

An mcmc.list object. An n.clones attribute is attached to the object, but unlike in jags.fit there is no updated.model attribute as it is equivalent to the input jags model object.

## End(Not run)

dc.fit

Iterative model fitting with data cloning

**Description**

jags.fit or bugs.fit is iteratively used to fit a model with increasing the number of clones.

**Usage**

dc.fit(data, params, model, inits, n.clones, 
multiply = NULL, unchanged = NULL, 
update = NULL, updatefun = NULL, initsfun = NULL, 
flavour = c(“jags”, “bugs”), n.chains = 3, ...)

**Arguments**

data A named list (or environment) containing the data.

params Character vector of parameters to be sampled. It can be a list of 2 vectors, 1st element is used as parameters to monitor, the 2nd is used as parameters to use in calculating the data cloning diagnostics.

model Character string (name of the model file), a function containing the model, or a custommodel object (see Examples).

inits Optional specification of initial values in the form of a list or a function (see Initialization at jags.model). If missing, will be treated as NULL and initial values will be generated automatically.
n.clones An integer vector containing the numbers of clones to use iteratively.
multiply Numeric or character index for list element(s) in the data argument to be multiplied by the number of clones instead of repetitions.
unchanged Numeric or character index for list element(s) in the data argument to be left unchanged.
update Numeric or character index for list element(s) in the data argument that has to be updated by updatefun in each iterations. This usually is for making priors more informative, and enhancing convergence. See Details and Examples.
updatefun A function to use for updating data[[update]]. It should take an 'mcmc.list' object as 1st argument, 2nd argument can be the number of clones. See Details and Examples.
initsfun A function to use for generating initial values, inits are updated by the object returned by this function from the second iteration. If initial values are not dependent on the previous iteration, this should be NULL, otherwise, it should take an 'mcmc.list' object as 1st argument, 2nd argument can be the number of clones. This feature is useful if latent nodes are provided in inits so it also requires to be cloned for subsequent iterations. See Details and Examples.
flavour If "jags", the function jags.fit is called. If "bugs", the function bugs.fit is called.
n.chains Number of chains to generate.
... Other values supplied to jags.fit, or bugs.fit, depending on the flavour argument.

Details

The function fits a JAGS/BUGS model with increasing numbers of clones, as supplied by the argument n.clones. Data cloning is done by the function dclone using the arguments multiply and unchanged. An updating function can be provided, see Examples.

Value

An object inheriting from the class 'mcmc.list'.

Author(s)

Peter Solymos, <solymos@ualberta.ca>, implementation is based on many discussions with Khurram Nadeem and Subhash Lele.

dc.parfit

Parallel model fitting with data cloning

Description

Iterative model fitting on parallel workers with different numbers of clones.
Usage

dc.parfit(cl, data, params, model, inits, n.clones,
  multiply=NULL, unchanged=NULL,
  update = NULL, updatefun = NULL, initsfun = NULL,
  flavour = c("jags", "bugs"), n.chains = 3,
  partype=c("balancing", "parchains", "both"), ...)

Arguments

cl A cluster object created by makeCluster, or an integer, see parDosa and evalParallelArgument.
data A named list (or environment) containing the data.
params Character vector of parameters to be sampled. It can be a list of 2 vectors, 1st element is used as parameters to monitor, the 2nd is used as parameters to use in calculating the data cloning diagnostics. (partype = "both" currently cannot handle params as list.)
model Character string (name of the model file), a function containing the model, or a custommodel object (see Examples).
inits Optional specification of initial values in the form of a list or a function (see Initialization at jags.model). If missing, will be treated as NULL and initial values will be generated automatically. If this is a function, it must be self containing, i.e. not having references to R objects outside of the function, or the objects should be exported with clusterExport before calling dc.parfit.
n.clones An integer vector containing the numbers of clones to use iteratively.
multiply Numeric or character index for list element(s) in the data argument to be multiplied by the number of clones instead of repetitions.
unchanged Numeric or character index for list element(s) in the data argument to be left unchanged.
update Numeric or character index for list element(s) in the data argument that has to be updated by updatefun in each iterations. This usually is for making priors more informative, and enhancing convergence. This argument is ignored if size balancing is used (default), and not ignored when multiple parallel chains are used.
updatefun A function to use for updating data[[update]]. It should take an 'mcmc.list' object as 1st argument, 2nd argument can be the number of clones. This argument is ignored if size balancing is used (default), and not ignored when multiple parallel chains are used.
initsfun A function to use for generating initial values, inits are updated by the object returned by this function from the second iteration. If initial values are not dependent on the previous iteration, this should be NULL, otherwise, it should take an 'mcmc.list' object as 1st argument, 2nd argument can be the number of clones. This feature is useful if latent nodes are provided in inits so it also requires to be cloned for subsequent iterations. The 1st argument of the initsfun function is ignored if partype != "parchains" but the function must have a first argument regardless, see Examples.
flavour  If "jags", the function jags.fit is called. If "bugs", the function bugs.fit is called (available with partype = "balancing" only). See Details.

partype  Type of parallel workload distribution, see Details.
n.chains  Number of chains to generate.
...  Other values supplied to jags.fit, or bugs.fit, depending on the flavour argument.

Details

The dc.parfit is a parallel computing version of dc.fit. After parallel computations, temporary objects passed to workers and the dclone package is cleaned up. It is not guaranteed that objects already on the workers and independently loaded packages are not affected. Best to start new instances beforehand.

partype="balancing" distributes each model corresponding to values in n.clones as jobs to workers according to size balancing (see snowWrapper). partype="parchains" makes repeated calls to jags.parfit for each value in n.clones. partype="both" also calls jags.parfit but each chain of each cloned model is distributed as separate job to the workers.

The vector n.clones is used to determine size balancing. If load balancing is also desired besides of size balancing (e.g. due to unequal performance of the workers, the option "dclone.LB" should be set to TRUE (by using options("dclone.LB" = TRUE)). By default, the "dclone.LB" option is FALSE for reproducibility reasons.

Some arguments from dc.fit are not available in parallel version (update, updatefun, initsfun) when size balancing is used (partype is "balancing" or "both"). These arguments are evaluated only when partype="parchains".

Size balancing is recommended if n.clones is a relatively long vector, while parallel chains might be more efficient when n.clones has few elements. For efficiency reasons, a combination of the two (partype="both") is preferred if cluster size allows it.

Only partype="balancing" is available for flavour="bugs".

Additionally loaded JAGS modules (e.g. "glm") need to be loaded to the workers.

Value

An object inheriting from the class 'mcmc.list'.

**dclone**

Cloning R objects

**Description**

Makes clones of R objects, that is values in the object are repeated \( n \) times, leaving the original structure of the object intact (in most of the cases).
Usage

dclone(x, n.clones=1, ...)  # Default S3 method:
dclone(x, n.clones = 1, attrib=TRUE, ...)  # S3 method for class 'dcdim'
dclone(x, n.clones = 1, attrib=TRUE, ...)  # S3 method for class 'dciid'
dclone(x, n.clones = 1, attrib=TRUE, ...)  # S3 method for class 'dctr'
dclone(x, n.clones = 1, attrib=TRUE, ...)  # S3 method for class 'list'
dclone(x, n.clones = 1,
       multiply = NULL, unchanged = NULL, attrib=TRUE, ...)
# S3 method for class 'environment'
dclone(x, n.clones = 1,
       multiply = NULL, unchanged = NULL, attrib=TRUE, ...)
dcdim(x, drop = TRUE, perm = NULL)
dciid(x, iid=character(0))
dctr(x)

Arguments

x              An R object to be cloned, or a cloned object to print.
n.clones      Number of clones.
multiply      Numeric or character index for list element(s) to be multiplied by n.clones instead of repetitions (as done by dclone.default).
unchanged     Numeric or character index for list element(s) to be left unchanged.
attrib        Logical, TRUE if attributes are to be attached.
drop          Logical, if TRUE, deletes the last dimension of an array if that have only one level.
perm          The subscript permutation value, if the cloning dimension is not the last.
iid           Character (or optionally numeric or logical). Column(s) to be treated as i.i.d. observations. Ignored when x is a vector.
...            Other arguments passed to function.

Details

dclone is a generic function for cloning objects. It is separate from rep, because there are different ways of cloning, depending on the BUGS code implementation:

(1) Unchanged: no cloning at all (for e.g. constants).
(2) Repeat: this is the most often used cloning method, repeating the observations row-wise as if there were more samples. The dctr option allows repeating the data column-wise.
(3) Multiply: sometimes it is enough to multiply the numbers (e.g. for Binomial distribution).
(4) Add dimension: under specific circumstances, it is easier to add another dimension for clones, but otherwise repeat the observations (e.g. in case of time series, or for addressing special indexing conventions in the BUGS code, see examples 

dcdim and dclone.dcdim).

(5) Repeat pattern (i.i.d.): this is useful for example when a grouping variable is considered, and more i.i.d. groups are to be added to the data set. E.g. \(c(1, 1, 2, 2)\) is to be cloned as \(c(1, 1, 2, 2, 3, 3, 4, 4)\) instead of \(c(1, 1, 2, 2, 1, 1, 2, 2)\).

Value

An object with class attributes "dclone" plus the original one(s). Dimensions of the original object might change according to \(n.\) clones. The function tries to take care of names, sometimes replacing those with the combination of the original names and an integer for number of clones.

\(\text{dcdim}\) sets the class attribute of an object to "\text{dcdim}\", thus \(\text{dclone}\) will clone the object by adding an extra dimension for the clones.

\(\text{dciid}\) sets the class attribute of an object to "\text{dciid}\", thus \(\text{dclone}\) will clone the object by treating columns defined by the \(\text{iid}\) argument as i.i.d. observations. These columns must be numeric. This aims to facilitates working with the \text{INLA} package to generate approximate marginals based on DC. Columns specified by \(\text{iid}\) will be replaced by an increasing sequence of values respecting possible grouping structure (see Examples).

Lists (i.e. BUGS data objects) are handled differently to enable element specific determination of the mode of cloning. This can be done via the unchanged and multiply arguments, or by setting the behaviour by the \text{dcdim} function.

Environments are coerced into a list, and return value is identical to \(\text{dclone}(\text{as.list}(x), \ldots)\).

Author(s)

Peter Solymos, \(<\text{solymos@ualberta.ca}>\), implementation is based on many discussions with Khurram Nadeem and Subhash Lele.

DcloneEnv

Manipulating dclone environments

Description

Manipulating dclone environments.

Usage

pullDcloneEnv(x, type = c("model", "results"))
pushDcloneEnv(x, value, type = c("model", "results"))
clearDcloneEnv(..., list = character(),
  type = c("model", "results"))
listDcloneEnv(type = c("model", "results"))
existsDcloneEnv(x, type = c("model", "results"),
  mode = "any", inherits = TRUE)

Arguments

x

a variable name, given as a character string. No coercion is done, and the first
element of a character vector of length greater than one will be used, with a
warning.
value  
a value to be assigned to \textit{x}.

type  
character, the type of environment to be accessed, see Details.

...  
the objects to be removed, as names (unquoted) or character strings (quoted).

list  
a character vector naming objects to be removed.

mode  
the mode or type of object sought: see the \texttt{exists}.

inherits  
logical, should the enclosing frames of the environment be searched?

Details

type = "model" manipulates the \texttt{.DcloneEnvModel} environment, which is meant to store temporary objects for model fitting with ‘snow’ type parallelism (see \texttt{parDosa} for the implementation). This is swiped clean after use.

Thetype = "results" manipulates the \texttt{.DcloneEnvResults} environment, which is meant to store result objects on the workers. This is \texttt{not} swiped clean after use.

\texttt{pullDcloneEnv} pulls an object from these environments, similar to \texttt{get} in effect.

\texttt{pushDcloneEnv} pushes an object to these environments, similar to \texttt{assign} in effect.

\texttt{clearDcloneEnv} removes object(s) from these environments, similar to \texttt{rm} in effect.

\texttt{listDcloneEnv} lists name(s) of object(s) in these environments, similar to \texttt{ls} in effect.

\texttt{existsDcloneEnv} tests if an object exists in these environments, similar to \texttt{exists} in effect.

Value

For \texttt{pullDcloneEnv}, the object found. If no object is found an error results.

\texttt{pushDcloneEnv} is invoked for its side effect, which is assigning \texttt{value} to the variable \texttt{x}.

For \texttt{clearDcloneEnv} its is the side effect of an object removed. No value returned.

\texttt{listDcloneEnv} returns a character vector.

\texttt{existsDcloneEnv} returns logical, \texttt{TRUE} if and only if an object of the correct name and mode is found.

\texttt{parDosa}
dcoptions

Setting Options

Description

Setting options.

Usage

dcoptions(...)

Arguments

... Arguments in tag = value form, or a list of tagged values. The tags must come from the parameters described below.

Details

dcoptions is a convenient way of handling options related to the package.

Value

When parameters are set by dcoptions, their former values are returned in an invisible named list. Such a list can be passed as an argument to dcoptions to restore the parameter values. Tags are the following:

- **autoburnin**: logical, to use in `gelman.diag` (default is `TRUE`).
- **diag**: critical value to use for data cloning convergence diagnostics, default is 0.05.
- **LB**: logical, should load balancing be used, default is `FALSE`.
- **overwrite**: logical, should existing model file be overwritten, default is `TRUE`.
- **rhat**: critical value for testing chain convergence, default is 1.1.
- **RNG**: parallel RNG type, either "none" (default), "RNGstream" or "SPRNG", see `clusterSetupRNG`.
- **verbose**: integer, should output be verbose (>0) or not (0), default is 1.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

Examples

```r
## set LB option, but store old value
ov <- dcoptions("LB"=TRUE)
## this is old value
ov
## this is new value
getOption("dcoptions")
## reset to old value
```
**dctable**

Retrieve descriptive statistics from fitted objects to evaluate convergence

**Description**

The function is used to retrieve descriptive statistics from fitted objects in order to evaluate convergence of the data cloning algorithm. This is best done via visual display of the results, separately for each parameters of interest.

**Usage**

```r
dctable(x, ...) ## Default S3 method:
dctable(x, ...) ## S3 method for class 'dctable'
plot(x, which = 1:length(x),
     type = c("all", "var", "log.var"),
     position = "topright", box.cex = 0.75, box.bg, ...)
extractdctable(x, ...)
## Default S3 method:
extractdctable(x, ...)

dcdiag(x, ...) ## Default S3 method:
dcdiag(x, ...) ## S3 method for class 'dcdiag'
plot(x, which = c("all", "lambda.max", "ms.error", "r.squared", "log.lambda.max"),
     position = "topright", ...)
extractdcdiag(x, ...)
## Default S3 method:
extractdcdiag(x, ...)
```

**Arguments**

- **x** An MCMC or a 'dctable' object.
- **...** Optionally more fitted model objects for function dctable.
- **which** What to plot. For dctable, character names or integer indices of the estimated parameters are accepted. for dcdiag it should be one of c("all", "lambda.max", "ms.error", "r.squared", "log.lambda.max")
- **type** Type of plot to be drawn. See Details.
position: Position for the legend, as for `legend`.

box.cex: Scaling factor for the interquartile boxes.

box.bg: Background color for the interquartile boxes.

Details

dctable returns the "dctable" attribute of the MCMC object, or if it is NULL, calculates the dctable summaries. If more than one fitted objects are provided, summaries are calculated for all objects, and results are ordered by the number of clones.

The `plot` method for dctable helps in graphical representation of the descriptive statistics. `type = "all"` results in plotting means, standard deviations and quantiles against the number of clones as boxplot. `type = "var"` results in plotting the scaled variances against the number of clones. In this case variances are divided by the variance of the model with smallest number of clones, \(\min(n\text{.clones})\). `type = "log.var"` is the same as "var", but on the log scale. Along with the values, the \(\min(n\text{.clones}) / n\text{.clones}\) line is plotted for reference.

Lele et al. (2010) introduced diagnostic measures for checking the convergence of the data cloning algorithm which are based on the joint posterior distribution and not only on single parameters. These include to calculate the largest eigenvalue of the posterior variance covariance matrix (\(\lambda_{\max}\) as returned by `lambdamax.diag`), or to calculate mean squared error (\(\text{ms.error}\)) and another correlation-like fit statistic (\(r_{squared}\)) based on a Chi-squared approximation (as returned by `chisq.diag`). The maximum eigenvalue reflects the degenerateness of the posterior distribution, while the two fit measures reflect if the Normal approximation is adequate. All three statistics should converge to zero as the number of clones increases. If this happens, different prior specifications are no longer influencing the results (Lele et al., 2007, 2010). These are conveniently collected by the dcdiag function.

**IMPORTANT!** Have you checked if different prior specifications lead to the same results?

Value

An object of class `dctable`. It is a list, and contains as many data frames as the number of parameters in the fitted object. Each data frame contains descriptives as the function of the number of clones.

dcdiag returns a data frame with convergence diagnostics.

The `plot` methods produce graphs as side effect.

Author(s)

Peter Solymos, <solymos@ualberta.ca>, implementation is based on many discussions with Khurram Nadeem and Subhash Lele.

    alpha[i] ~ dnorm(0, 1/sigma^2)
  }
  ```
## errlines

### Description

The function plots error bars to existing plot.

### Usage

```r
errlines(x, ...)  
## Default S3 method:
errlines(x, y, type = "l", code = 0,  
        width = 0, vertical = TRUE, col = 1, bg = NA, ...)
```

### Arguments

- **x**: Numeric vector with coordinates along the horizontal axis (if `vertical = FALSE`, this sets the vertical axis).
- **y**: A matrix-like object with 2 columns for lower and upper values on the vertical axis (if `vertical = FALSE`, this sets the horizontal axis).
- **type**: Character, "l" for lines, "b" for boxes to be drawn.
- **code**: Integer code, determining the kind of ticks to be drawn. See Details.
The `errlines` function uses `lines` to draw error bars to existing plot when `type = "l"`. `polygon` is used for boxes when `type = "b"`.

If `code = 0` no ticks are drawn, if `code = 1`, only lower ticks are drawn, if `code = 2` only lower ticks are drawn, if `code = 3` both lower and upper ticks are drawn.

**Examples**

```r
x <- 1:10
a <- rnorm(10,10)
a <- a[order(a)]
b <- runif(10)
y <- cbind(a-b, a+b+rev(b))
opar <- par(mfrow=c(2, 3))
plot(x, a, ylim = range(y))
errlines(x, y)
plot(x, a, ylim = range(y))
errlines(x, y, width = 0.5, code = 1)
plot(x, a, ylim = range(y), col = 1:10)
errlines(x, y, width = 0.5, code = 3, col = 1:10)
plot(x, a, ylim = range(y))
errlines(x, y, width = 0.5, code = 2, type = "b")
plot(x, a, ylim = range(y))
errlines(x, y, width = 0.5, code = 3, type = "b")
plot(x, a, ylim = range(y), type = "n")
errlines(x, y, width = 0.5, code = 3, type = "b", bg = 1:10)
errlines(x, cbind(a-b/2, a+b/2+rev(b)/2))
points(x, a)
par(opar)
```
**evalParallelArgument**  
*Evaluates parallel argument*

---

**Description**

Evaluates parallel argument.

**Usage**

```r
evalParallelArgument(cl, quit = FALSE)
```

**Arguments**

- **cl**: NULL, a cluster object or an integer. Can be missing.
- **quit**: Logical, whether it should stop with error when ambiguous parallel definition is found (conflicting default environmental variable settings).

**Value**

NULL for sequential evaluation or the original value of `cl` if parallel evaluation is meaningful.

**Author(s)**

Peter Solymos, <solymos@ualberta.ca>

**Examples**

```r
evalParallelArgument()
evalParallelArgument(NULL)
evalParallelArgument(1)
evalParallelArgument(2)
c1 <- makePSOCKcluster(2)
evalParallelArgument(c1)
stopCluster(c1)
oop <- options("mc.cores"=2)
evalParallelArgument()
options(oop)
```
**jags.fit**  
*Fit JAGS models with cloned data*

**Description**

Convenient functions designed to work well with cloned data arguments and JAGS.

**Usage**

```r
ejags.fit(data, params, model, inits = NULL, n.chains = 3,
          n.adapt = 1000, n.update = 1000, thin = 1, n.iter = 5000,
          updated.model = TRUE, ...)
```

**Arguments**

- `data` A named list or environment containing the data. If an environment, `data` is coerced into a list.
- `params` Character vector of parameters to be sampled.
- `model` Character string (name of the model file), a function containing the model, or a custommodel object (see Examples).
- `inits` Optional specification of initial values in the form of a list or a function (see Initialization at `jags.model`). If NULL, initial values will be generated automatically. It is an error to supply an initial value for an observed node.
- `n.chains` Number of chains to generate.
- `n.adapt` Number of steps for adaptation.
- `n.update` Number of updates before iterations. It is usually a bad idea to use `n.update=0` if `n.adapt>0`, so a warning is issued in such cases.
- `thin` Thinning value.
- `n.iter` Number of iterations.
- `updated.model` Logical, if the updated model should be attached as attribute (this can be used to further update if convergence was not satisfactory, see `updated.model` and `update.mcmc.list`).
- `...` Further arguments passed to `coda.samples`, and `update.jags` (e.g. the progress.bar argument).

**Value**

An `mcmc.list` object. If data cloning is used via the `data` argument, summary returns a modified summary containing scaled data cloning standard errors (scaled by `sqrt(n.clones)`), see `dcsd`, and `Rhat` values (as returned by `gelman.diag`).

**Author(s)**

Peter Solymos, <solymos@ualberta.ca>
See Also

Underlying functions: `jags.model, update.jags, coda.samples`

Parallel chain computations: `jags.parfit`

Methods: `dcasd, confint.mcmc.list.dc, coef.mcmc.list, quantile.mcmc.list, vcov.mcmc.list, dcd

Examples

```r
## Not run:
if (require(rjags)) {
## simple regression example from the JAGS manual
jfun <- function() {
  for (i in 1:N) {
    Y[i] ~ dnorm(mu[i], tau)
    mu[i] <- alpha + beta * (x[i] - x.bar)
  }
  x.bar <- mean(x[])
  alpha ~ dnorm(0.0, 1.0E-4)
  beta ~ dnorm(0.0, 1.0E-4)
  sigma <- 1.0/sqrt(tau)
  tau ~ dgamma(1.0E-3, 1.0E-3)
}
## data generation
set.seed(1234)
N <- 100
alpha <- 1
beta <- -1
sigma <- 0.5
x <- runif(N)
linpred <- crossprod(t(model.matrix(~x)), c(alpha, beta))
Y <- rnorm(N, mean = linpred, sd = sigma)
## list of data for the model
jdata <- list(N = N, Y = Y, x = x)
## what to monitor
jpara <- c("alpha", "beta", "sigma")
## fit the model with JAGS
regmod <- jags.fit(jdata, jpara, jfun, n.chains = 3)
## model summary
summary(regmod)
## data cloning
dcdata <- dclone(jdata, 5, multiply = "N")
dcmo <- jags.fit(dcdata, jpara, jfun, n.chains = 3)
summary(dcmo)
}
## End(Not run)
```
Description

Does the same job as `jags.fit`, but parallel chains are run on parallel workers, thus computations can be faster (up to \(1/n\text{. chains}\)) for long MCMC runs.

Usage

```r
ejags.parfit(cl, data, params, model, inits = NULL, n.chains = 3, ...)
```

Arguments

- **cl**: A cluster object created by `makeCluster`, or an integer, see `parDosa` and `evalParallelArgument`.
- **data**: A named list or environment containing the data. If an environment, `data` is coerced into a list.
- **params**: Character vector of parameters to be sampled.
- **model**: Character string (name of the model file), a function containing the model, or a `custommodel` object (see Examples).
- **inits**: Specification of initial values in the form of a list or a function, can be missing. Missing value setting can include RNG seed information, see Initialization at `jags.model`. If this is a function and using 'snow' type cluster as cl argument, the function must be self containing, i.e. not having references to R objects outside of the function, or the objects should be exported with `clusterExport` before calling `jags.parfit`. Forking type parallelism does not require such attention.
- **n.chains**: Number of chains to generate, must be higher than 1. Ideally, this is equal to the number of parallel workers in the cluster.
- **...**: Other arguments passed to `jags.fit`.

Details

Chains are run on parallel workers, and the results are combined in the end.

No update method is available for parallel `mcmc.list` objects. See `parUpdate` and related parallel functions (`parJagsModel, parCodaSamples`) for such purpose.

Additionally loaded JAGS modules (e.g. "glm", "lecuyer") need to be loaded to the workers when using 'snow' type cluster as cl argument. See Examples.

The use of the "lecuyer" module is recommended when running more than 4 chains. See Examples and `parallel.inits`.

Value

An `mcmc.list` object.

## End(Not run)

---

**jagsModel**

Create a JAGS model object

**Description**

`jagsModel` is used to create an object representing a Bayesian graphical model, specified with a BUGS-language description of the prior distribution, and a set of data. This function uses `jags.model` but keeps track of data cloning information supplied via the `data` argument. The model argument can also accept functions or `custommodel` objects.

**Usage**

```r
jagsModel(file, data=sys.frame(sys.parent()), inits, n.chains = 1,
n.adapt=1000, quiet=FALSE)
```

**Arguments**

- **file**: the name of the file containing a description of the model in the JAGS dialect of the BUGS language. Alternatively, `file` can be a readable text-mode connection, or a complete URL. It can be also a function or a `custommodel` object.
- **data**: a list or environment containing the data. Any numeric objects in `data` corresponding to node arrays used in `file` are taken to represent the values of observed nodes in the model.
- **inits**: optional specification of initial values in the form of a list or a function. If omitted, initial values will be generated automatically. It is an error to supply an initial value for an observed node.
- **n.chains**: the number of chains for the model.
- **n.adapt**: the number of iterations for adaptation. See `adapt` for details. If `n.adapt = 0` then no adaptation takes place.
- **quiet**: if `TRUE` then messages generated during compilation will be suppressed.
lambdamax.diag

Value

parJagsModel returns an object inheriting from class jags which can be used to generate dependent samples from the posterior distribution of the parameters.

An object of class jags is a list of functions that share a common environment, see jags.model for details.

An n.clones attribute is attached to the object when applicable.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

See Also

See example on help page of codaSamples.

Parallel version: parJagsModel

lambdamax.diag

Data Cloning Diagnostics

Description

These functions calculates diagnostics for evaluating data cloning convergence.

Usage

lambdamax.diag(x, ...)
## S3 method for class 'mcmc.list'
lambdamax.diag(x, ...)

chisq.diag(x, ...)
## S3 method for class 'mcmc.list'
chisq.diag(x, ...)

Arguments

x An object of class mcmc or mcmc.list.
...

Other arguments to be passed.
Details

These diagnostics can be used to test for the data cloning convergence (Lele et al. 2007, 2010). Asymptotically the posterior distribution of the parameters approaches a degenerate multivariate normal distribution. As the distribution is getting more degenerate, the maximal eigenvalue ($\lambda_{\text{max}}$) of the unscaled covariance matrix is decreasing. There is no critical value under which $\lambda_{\text{max}}$ is good enough. By default, 0.05 is used (see getOption("dclone")$diag).

Another diagnostic tool is to check if the joint posterior distribution is multivariate normal. It is done by chisq.diag as described by Lele et al. (2010).

Value

lambdamax.diag returns a single value, the maximum of the eigenvalues of the unscaled variance covariance matrix of the estimated parameters.

chisq.diag returns two test statistic values (mean squared error and r-squared) with empirical and theoretical quantiles.

Author(s)

Khurram Nadeem, <knadeem@math.ualberta.ca>
Peter Solymos, <solymos@ualberta.ca>

Eigen decomposition: eigen

Examples

data(regmod)
lambdamax.diag(regmod)
chisq.diag(regmod)
make.symmetric

Make a square matrix symmetric by averaging.

Description

Matrix symmetry might depend on numerical precision issues. The older version of JAGS had a bug related to this issue for multivariate normal nodes. This simple function can fix the issue, but new JAGS versions do not require such intervention.

Usage

make.symmetric(x)

Arguments

x A square matrix.

Details

The function takes the average as \((x[i, j] + x[j, i]) / 2\) for each off diagonal cells.

Value

A symmetric square matrix.

Note

The function works for any matrix, even for those not intended to be symmetric.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

Examples

```r
x <- as.matrix(as.dist(matrix(1:25, 5, 5)))
diag(x) <- 100
x[lower.tri(x)] <- x[lower.tri(x)] - 0.1
x[upper.tri(x)] <- x[upper.tri(x)] + 0.1
x
make.symmetric(x)
```
mclapplySB

Size balancing version of mclapply

Description
mclapplySB is a size balancing version of mclapply.

Usage
mclapplySB(X, FUN, ..., mc.preschedule = TRUE, mc.set.seed = TRUE,
          mc.silent = FALSE, mc.cores = 1L,
          mc.cleanup = TRUE, mc.allow.recursive = TRUE,
          size = 1)

Arguments

- **X**  
  a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by as.list.

- **FUN**  
  the function to be applied to each element of \( X \)

- **...**  
  optional arguments to FUN

- **mc.preschedule**  
  see mclapply

- **mc.set.seed**  
  see mclapply

- **mc.silent**  
  see mclapply

- **mc.cores**  
  The number of cores to use, i.e. how many processes will be spawned (at most)

- **mc.cleanup**  
  see mclapply

- **mc.allow.recursive**  
  see mclapply

- **size**  
  Vector of problem sizes (or relative performance information) corresponding to elements of \( X \) (recycled if needed). The default 1 indicates equality of problem sizes.

Details
mclapply gives details of the forking mechanism.
mclapply is used unmodified if sizes of the jobs are equal (length(unique(size)) == 1). Size balancing (as described in snowWrapper) is used to balance workload on the child processes otherwise.

Value
A list.
Author(s)

Peter Solymos

Methods for the 'mcmc.list' class

Description

Methods for 'mcmc.list' objects.

Usage

dcsd(object, ...)  
## S3 method for class 'mcmc.list'  
dcsd(object, ...)  
## S3 method for class 'mcmc.list'  
coef(object, ...)  
## S3 method for class 'mcmc.list.dc'  
confint(object, parm, level = 0.95, ...)  
## S3 method for class 'mcmc.list'  
vcov(object, ...)  
## S3 method for class 'mcmc.list.dc'  
vcov(object, invfisher = TRUE, ...)  
## S3 method for class 'mcmc.list'  
quantile(x, ...)

Arguments

x, object  
MCMC object to be processed.

parm  
A specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.

level  
The confidence level required.

...  
Further arguments passed to functions.

invfisher  
Logical, if the inverse of the Fisher information matrix (TRUE) should be returned instead of the variance-covariance matrix of the joint posterior distribution (FALSE).
Value

dcsd returns the data cloning standard errors of a posterior MCMC chain calculated as standard deviation times the square root of the number of clones.

The coef method returns mean of the posterior MCMC chains for the monitored parameters.

The confint method returns Wald-type confidence intervals for the parameters assuming asymptotic normality.

The vcov method returns the inverse of the Fisher information matrix (invfisher = TRUE) or the covariance matrix of the joint posterior distribution (invfisher = FALSE). The invfisher is valid only for mcmc.list.dc (data cloned) objects.

The quantile method returns quantiles for each variable.

Note

Some functions only available for the 'mcmc.list.dc' class which inherits from class 'mcmc.list'.

### Description

Conveniently calculates statistics for mcmc.list objects.

### Usage

```r
mcmcapply(x, FUN, ...)
```

**S3 method for class 'mcmc.list'**

```r
stack(x, ...)
```

### Arguments

- `x`: Objects of class `mcmc.list`.
- `FUN`: A function to be used in the calculations, returning a single value.
- `...`: Other arguments passed to `FUN`.

### Details

`mcmcapply` returns a certain statistic based on `FUN` after coercing into a matrix. `FUN` can be missing, in this case `mcmcapply` is equivalent to calling `as.matrix` on an `mcmc.list` object.

`stack` can be used to concatenate `mcmc.list` objects into a single vector along with index variables indicating where each observation originated from (e.g. iteration, variable, chain).

### Value

- `mcmcapply` returns statistic value for each variable based on `FUN`, using all values in all chains of the MCMC object.
- `stack` returns a data frame with columns: iter, variable, chain, value.

### Author(s)

Peter Solymos, <solymos@ualberta.ca>
Examples

```
data(regmod)
mcmcapply(regmod, mean)
mcmcapply(regmod, sd)

x <- stack(regmod)
head(x)
summary(x)
library(lattice)
xyplot(value ~ iter | variable, data=x,
       type="l", scales = "free", groups=chain)
```

<table>
<thead>
<tr>
<th>nclones</th>
<th>Number of Clones</th>
</tr>
</thead>
</table>

Description

Retrieves the number of clones from an object.

Usage

```
nclones(x, ...)
```

## Default S3 method:
nclones(x, ...)

## S3 method for class 'list'
nclones(x, ...)

Arguments

- `x` An object.
- `...` Other arguments to be passed.

Value

Returns the number of clones, or NULL.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

See Also

dclone

Examples

```
x <- dclone(1:10, 10)
nclones(x)
nclones(1:10) # this is NULL
```
Description

The data set contains observations (point counts) of 198 sites of the Alberta Biodiversity Monitoring Institute.

- count: integer, ovenbird counts per site.
- site, year: numeric, site number and year of data collection.
- ecosite: factor with 5 levels, ecological categorization of the sites.
- uplow: factor with 2 levels, ecological categorization of the sites (same as ecosite but levels are grouped into upland and lowland).
- dsucc, dalien, thd: numeric, percentage of successional, alienating and total human disturbance based on interpreted 3 x 7 km photoplots centered on each site.
- long, lat: numeric, public longitude/latitude coordinates of the sites.

Usage

```r
data(ovenbird)
```

Source

Alberta Biodiversity Monitoring Institute, http://www.abmi.ca

Examples

```r
data(ovenbird)
summary(ovenbird)
str(ovenbird)
```

Description

A matrix of scatterplots is produced.

Usage

```r
## S3 method for class 'mcmc.list'
pairs(x, n = 25, col = 1:length(x),
      col.hist = "gold", col.image = terrain.colors(50),
      density = TRUE, contour = TRUE, mean = TRUE, ...)
```
**Arguments**

- **x**
  - an `mcmc.list` object.

- **n**
  - number of grid points in each direction for two-dimensional kernel density estimation. Can be scalar or a length-2 integer vector.

- **col**
  - color for chains in upper panel scatterplots.

- **col.hist**
  - color for histogram fill in diagonal panels.

- **col.image**
  - color palette for image plot in lower panel scatterplots.

- **density**
  - logical, if image plot based on the two-dimensional kernel density estimation should be plotted in lower panel.

- **contour**
  - logical, if contour plot based on the two-dimensional kernel density estimation should be plotted in lower panel.

- **mean**
  - logical, if lines should indicate means of the posterior densities in the panels.

- **...**
  - additional graphical parameters/arguments.

**Details**

The function produces a scatterplot matrix for `mcmc.list` objects. Diagonal panels are posterior densities with labels and rug on the top. Upper panels are pairwise bivariate scatterplots with coloring corresponding to chains, thus highlighting mixing properties although not as clearly as trace plots. Lower panels are two-dimensional kernel density estimates based on `kde2d` function of `MASS` package using `image` and `contour`.

**Value**

The function returns `NULL` invisibly and produces a plot as a side effect.

**Author(s)**

Peter Solymos, <solymos@ualberta.ca>

**See Also**

`pairs`, `plot.mcmc.list`

Two-dimensional kernel density estimation: `kde2d` in `MASS` package

**Examples**

```r
data(regmod)
pairs(regmod)
```
**parallel.inits**

*Parallel RNGs for initial values*

**Description**

This function takes care of initial values with safe RNGs based on `parallel.seeds` of the `rjags` package.

**Usage**

```
parallel.inits(inits, n.chains)
```

**Arguments**

- `inits` Initial values (see Initialization at `jags.model`). If NULL, an empty list of length `n.chains` will be generated and seeded (RNG type and seed).
- `n.chains` Number of chains to generate.

**Details**

Initial values are handled similar to as it is done in `jags.model`.

RNGs are based on values returned by `parallel.seeds`.

If the "lecuyer" JAGS module is active, RNGs are based on the "lecuyer::RngStream" factory, otherwise those are based on the "base::BaseRNG" factory.

**Value**

Returns a list of initial values with RNGs.

**Author(s)**

Peter Solymos, <solymos@ualberta.ca>. Based on Martyn Plummer's `parallel.seeds` function and code in `jags.model` for initial value handling in the `rjags` package.

**See Also**

- `parallel.seeds, jags.model`
- This seeding function is used in all of `dclone`'s parallel functions that do initialization: `parJagsModel, jags.parfit, dc.parfit`
parCodaSamples

Examples

if (require(rjags)) {
  ## "base::BaseRNG" factory.
  parallel.inits(NULL, 2)
  ## "lecuyer::RngStream" factory
  load.module("lecuyer")
  parallel.inits(NULL, 2)
  unload.module("lecuyer")
  ## some non NULL inits specifications
  parallel.inits(list(a=0), 2)
  parallel.inits(list(list(a=0), list(a=0)), 2)
  parallel.inits(function() list(a=0), 2)
  parallel.inits(function(chain) list(a=chain), 2)
}

parCodaSamples

Generate posterior samples in 'mcmc.list' format on parallel workers

Description

This function sets a trace monitor for all requested nodes, updates the model on each workers. Finally, it return the chains to the master and coerces the output to a single mcmc.list object.

Usage

parCodaSamples(cl, model, variable.names, n.iter, thin = 1, ...)

Arguments

c1 A cluster object created by makeCluster, or an integer. It can also be NULL, see snowWrapper.
model character, name of a jags model object
variable.names a character vector giving the names of variables to be monitored
n.iter number of iterations to monitor
thin thinning interval for monitors
... optional arguments that are passed to the update method for jags model objects

Value

An mcmc.list object with possibly an n.clones attribute.

  stopifnot(2==nchain(m2))
  nclones(m2)
  stopCluster(cl)
}
```

## End(Not run)
**Description**

`parDosa` is a wrapper function around many functionalities of the `parallel` and `snow` packages. It is designed to work closely with MCMC fitting functions, e.g. can easily be called from inside of a function.

This function is replacing the `snowWrapper` function which is temporarily retained for compatibility.

**Usage**

```r
parDosa(cl, seq, fun, cldata,
lib = NULL, dir = NULL, evalq=NULL,
size = 1, balancing = c("none", "load", "size", "both"),
rng.type = c("none", "RNGstream", "SPRNG"),
cleanup = TRUE, unload = FALSE, ...)
```

**Arguments**

- `cl` A cluster object created by `makeCluster`, or an integer. It can also be `NULL`, see Details.
- `seq` A vector to split.
- `fun` A function or character string naming a function.
- `cldata` A list containing data. This list is then exported to the cluster by `clusterExport`. It is stored in a hidden environment. Data in `cldata` can be used by `fun`.
- `lib` Character, name of package(s). Optionally packages can be loaded onto the cluster. More than one package can be specified as character vector. Packages already loaded are skipped.
- `dir` Working directory to use, if `NULL` working directory is not set on workers (default). Can be a vector to set different directories on workers.
- `evalq` Character, expressions to evaluate, e.g. for changing global options (passed to `clusterevalq`). More than one expressions can be specified as character vector.
- `balancing` Character, type of balancing to perform (see Details).
- `size` Vector of problem sizes (or relative performance information) corresponding to elements of `seq` (recycled if needed). The default 1 indicates equality of problem sizes.
- `rng.type` Character, "none" or the type of RNG on the workers (see `clusterSetupRNG`). The logical value !(`rng.type` == "none") is used for forking (e.g. when `cl` is integer).
- `cleanup` logical, if `cldata` should be removed from the workers after applying `fun`. If `TRUE`, effects of `dir` argument is also cleaned up.
- `unload` logical, if `pkg` should be unloaded after applying `fun`.  

---

**parDosa**

*Parallel wrapper function to call from within a function*
... Other arguments of fun, that are simple values and not objects. (Arguments passed as objects should be specified in cldata, otherwise those are not exported to the cluster by this function.)

Details

The function uses 'snow' type clusters when cl is a cluster object. The function uses 'multicore' type forking (shared memory) when cl is an integer. The value from getOption("mc.cores") is used if the argument is NULL.

The function sets the random seeds, loads packages lib onto the cluster, sets the working directory as dir, exports cldata and evaluates fun on seq.

No balancing (balancing = "none") means, that the problem is splitted into roughly equal subsets, without respect to size (see clusterSplit). This splitting is deterministic (reproducible).

Load balancing (balancing = "load") means, that the problem is not splitted into subsets a priori, but subsequent items are placed on the worker which is empty (see clusterApplyLB for load balancing). This splitting is non-deterministic (might not be reproducible).

Size balancing (balancing = "size") means, that the problem is splitted into subsets, with respect to size (see clusterSplitSB and parLapplySB). In size balancing, the problem is re-ordered from largest to smallest, and then subsets are determined by minimizing the total approximate processing time. This splitting is deterministic (reproducible).

Size and load balancing (balancing = "both") means, that the problem is re-ordered from largest to smallest, and then undeterministic load balancing is used (see parLapplySLB). If size is correct, this is identical to size balancing. This splitting is non-deterministic (might not be reproducible).

Value

Usually a list with results returned by the cluster.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

Size balancing: parLapplySB, parLapplySLB, mclapplySB

Optimizing the number of workers: clusterSize, plotClusterSize.

parDosa is used internally by parallel dclone functions: jags.parfit, dc.parfit, parJagsModel, parUpdate, parCodaSamples.

parDosa manipulates specific environments described on the help page DcloneEnv.
parJagsModel  

Create a JAGS model object on parallel workers

Description
parJagsModel is used to create an object representing a Bayesian graphical model, specified with a BUGS-language description of the prior distribution, and a set of data.

Usage
parJagsModel(cl, name, file, data=sys.frame(sys.parent()),
              inits, n.chains = 1, n.adapt=1000, quiet=FALSE)

Arguments
cl  A cluster object created by makeCluster, or an integer. It can also be NULL, see snowWrapper. Size of the cluster must be equal to or larger than n.chains.
name  character, name for the model to be assigned on the workers.
file  the name of the file containing a description of the model in the JAGS dialect of the BUGS language. Alternatively, file can be a readable text-mode connection, or a complete URL. It can be also a function or a custommodel object.
data  a list or environment containing the data. Any numeric objects in data corresponding to node arrays used in file are taken to represent the values of observed nodes in the model
inits  optional specification of initial values in the form of a list or a function (see Initialization on help page of jags.model). If omitted, initial values will be generated automatically. It is an error to supply an initial value for an observed node.
n.chains  the number of parallel chains for the model
n.adapt  the number of iterations for adaptation. See adapt for details. If n.adapt = 0 then no adaptation takes place.
quiet  if TRUE then messages generated during compilation will be suppressed. Effect of this argument is not visible on the master process.

Value
parJagsModel returns an object inheriting from class jags which can be used to generate dependent samples from the posterior distribution of the parameters. These jags models are residing on the workers, thus updating/sampling is possible.

Length of cl must be equal to or greater than n.chains. RNG seed generation takes place first on the master, and chains then initialized on each worker by distributing inits and single chained models.

An object of class jags is a list of functions that share a common environment, see jags.model for details. Data cloning information is attached to the returned object if data argument has n.clones attribute.
Author(s)

Peter Solymos, <solymos@ualberta.ca>

See example on help page of \texttt{parCodaSamples}.

\begin{itemize}
\item \texttt{parLoadModule}\hfill \textit{Dynamically load JAGS modules on parallel workers}
\end{itemize}

Description

A JAGS module is a dynamically loaded library that extends the functionality of JAGS. These functions load and unload JAGS modules and show the names of the currently loaded modules on parallel workers.

Usage

\begin{verbatim}
parLoadModule(cl, name, path, quiet=FALSE)
parUnloadModule(cl, name, quiet=FALSE)
parListModules(cl)
\end{verbatim}

Arguments

\begin{description}
\item [cl] a cluster object created by the \texttt{parallel} (or \texttt{snow}) package.
\item [name] character, name of the module to be loaded
\item [path] file path to the location of the DLL. If omitted, the option \texttt{jags.moddir} is used to locate the modules. It can be a vector of length \texttt{length(cl)} to set different DLL locations on each worker
\item [quiet] a logical. If \texttt{TRUE}, no message will be printed about loading the module
\end{description}

Author(s)

Peter Solymos, <solymos@ualberta.ca>

See Also

\begin{verbatim}
list.modules, load.module, unload.module
\end{verbatim}
Examples

```r
## Not run:
if (require(rjags)) {
  cl <- makePSOCKcluster(3)
  parListModules(cl)
  parLoadModule(cl, "glm")
  parListModules(cl)
  parUnloadModule(cl, "glm")
  parListModules(cl)
  stopCluster(cl)
}

## End(Not run)
```

Description

JAGS modules contain factory objects for samplers, monitors, and random number generators for a JAGS model. These functions allow fine-grained control over which factories are active on parallel workers.

Usage

```r
parListFactories(cl, type)
parSetFactory(cl, name, type, state)
```

Arguments

- `cl`: a cluster object created by the `parallel` (or `snow`) package.
- `name`: name of the factory to set
- `type`: type of factory to query or set. Possible values are "sampler", "monitor", or "rng"
- `state`: a logical. If TRUE then the factory will be active, otherwise the factory will become inactive.

Value

`parListFactories` returns a list of data frame with two columns per each worker, the first column shows the names of the factory objects in the currently loaded modules, and the second column is a logical vector indicating whether the corresponding factory is active or not.

`sparStFactory` is called to change the future behaviour of factory objects. If a factory is set to inactive then it will be skipped.
Note

When a module is loaded, all of its factory objects are active. This is also true if a module is unloaded and then reloaded.

Peter Solymos, <solymos@ualberta.ca>

See Also

listNmodules, setNfactory

Examples

```r
## Not run:
if (require(rjags)) {
  cl <- makePSOCKcluster(3)
  parListFactories(cl, "sampler")
  parListFactories(cl, "monitor")
  parListFactories(cl, "rng")
  parSetFactory(cl, "base::Slice", "sampler", FALSE)
  parListFactories(cl, "sampler")
  parSetFactory(cl, "base::Slice", "sampler", TRUE)
  stopCluster(cl)
}
```

## End(Not run)

---

`parUpdate`  
*Update jags models on parallel workers*

Description

Update the Markov chain associated with the model on parallel workers.

Usage

`parUpdate(cl, object, n.iter=1, ...)`

Arguments

- `cl`  
  A cluster object created by `makeCluster`, or an integer. It can also be NULL, see `snowWrapper`.

- `object`  
  character, name of a jags model object

- `n.iter`  
  number of iterations of the Markov chain to run

- `...`  
  additional arguments to the update method, see `update.jags`
Value

The `parUpdate` function modifies the original object on parallel workers and returns `NULL`.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

```
alpha <- 1
beta <- -1
sigma <- 0.5
x <- runif(N)
linpred <- crossprod(t(model.matrix(~x)), c(alpha, beta))
Y <- rnorm(N, mean = linpred, sd = sigma)
## list of data for the model
jdata <- list(N = N, Y = Y, x = x)
## what to monitor
jpara <- c("alpha", "beta", "sigma")
## fit the model with JAGS
regmod <- jags.fit(jdata, jpara, jfun, n.chains = 3,
                   updated.model = FALSE)
## End(Not run)

snowWrapper  Parallel wrapper function to call from within a function

Description
This function is now replaced by parDosa.

Usage
snowWrapper(cl, seq, fun,
             cldata, name = "cldata", use.env=FALSE,
             lib = NULL, dir = NULL, evalq=NULL,
             size = 1, balancing = c("none", "load", "size", "both"),
             rng.type = c("none", "RNGstream", "SPRNG"),
             cleanup = TRUE, unload = FALSE, envir = .GlobalEnv, ...)

Arguments
cl  A cluster object created by makeCluster, or an integer. It can also be NULL, see Details.
seq A vector to split.
fun A function or character string naming a function.
cldata A list containing data. This will be assigned to an object name in the global environment (an already existing object with same name will be saved and replaced back in the end). This list is then exported to the cluster by clusterExport. Data in cldata can be used by fun.
name Character, the name of cldata as to be assigned to the global environment and used in fun.
use.env Logical, if name is to be treated as a list object or an environment.
lib

Character, name of package(s). Optionally packages can be loaded onto the cluster. More than one package can be specified as character vector. Packages already loaded are skipped.

dir

Working directory to use, if NULL working directory is not set on workers (default). Can be a vector to set different directories on workers.

evalq

Character, expressions to evaluate, e.g. for changing global options (passed to \texttt{clusterEvalQ}). More than one expressions can be specified as character vector.

balancing

Character, type of balancing to perform (see Details).

size

Vector of problem sizes (or relative performance information) corresponding to elements of \texttt{seq} (recycled if needed). The default 1 indicates equality of problem sizes.

rng.type

Character, "none" or the type of RNG on the workers (see \texttt{clusterSetupRNG}). The logical value !(\texttt{rng.type} == "none") is used for forking (e.g. when \texttt{cl} is integer).

cleanup

logical, if cl\texttt{data} should be removed from the workers after applying fun. If \texttt{TRUE}, effects of \texttt{dir} argument is also cleaned up.

unload

logical, if pkg should be unloaded after applying fun.

envir

environment to use when assigning data values.

...

Other arguments of fun, that are simple values and not objects. (Arguments passed as objects should be specified in cl\texttt{data}, otherwise those are not exported to the cluster by this function.)

Value

Usually a list with results returned by the cluster.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

See Also

This function is now replaced by \texttt{parDosa}.

\begin{verbatim}
update.mcmc.list  Automatic updating of an MCMC object
\end{verbatim}

Description

Automatic updating of an MCMC object until a desired statistic value reached.

Usage

\begin{verbatim}
updated.model(object, ...)
## S3 method for class 'mcmc.list'
update(object, fun,
       times = 1, n.update = 0, n.iter, thin, ...)
\end{verbatim}
Arguments

object  A fitted MCMC object ('mcmc.list' class for example), with "updated.model" attribute.

fun      A function that evaluates convergence of the MCMC chains, must return logical result. See Examples. The iterative updating quits when return value is TRUE. Can be missing, in which case there is no stopping rule.

times Number of times the updating should be repeated. If fun returns TRUE, updating is finished and MCMC object is returned.

n.update Number of updating iterations. The default 0 indicates, that only n.iter iterations are used.

n.iter Number of iterations for sampling and evaluating fun. If missing, value is taken from object.

thin Thinning value. If missing, value is taken from object.

... Other arguments passed to coda.samples.

Details

updated.model can be used to retrieve the updated model from an MCMC object fitted via the function jags.fit and dc.fit (with flavour = "jags"). The update method is a wrapper for this purpose, specifically designed for the case when MCMC convergence is problematic. A function is evaluated on the updated model in each iteration of the updating process, and an MCMC object is returned when iteration ends, or when the evaluated function returns TRUE value.

n.update and n.iter can be vectors, if lengths are shorter then times, values are recycled.

Data cloning information is preserved.

Value

updated.model returns the state of the JAGS model after updating and sampling. This can be further updated by the function update.jags and sampled by coda.samples if convergence diagnostics were not satisfactory.

update returns an MCMC object with "updated.model" attribute.

Author(s)

Peter Solymos, <solymos@ualberta.ca>

See Also

jags.fit, coda.samples, update.jags

Examples

## Not run:
## simple regression example from the JAGS manual
jfun <- function() {
  for (i in 1:N) {
    Y[i] ~ dnorm(mu[i], tau)
write.jags.model

Write and remove model file

Description

Writes or removes a BUGS model file to or from the hard drive.

Usage

write.jags.model(model, filename = "model.txt", digits = 5,
                     dir = getwd(), overwrite = getOption("dcoptions")$overwrite)
clean.jags.model(filename = "model.bug", dir = getwd())
custommodel(model, exclude = NULL, digits = 5)
Arguments

- **model**: JAGS model to write onto the hard drive (see Example). For `write.jags.model`, it can be name of a file or a function, or it can be an 'custommodel' object returned by `custommodel`. `custommodel` can take its `model` argument as function. If `model` is not function, its is coerced as character.

- **digits**: Number of significant digits used in the output.

- **filename**: Character, the name of the file to write/remove. It can be a `link{connection}`.

- **dir**: Optional argument for directory where to write or look for the file to remove.

- **overwrite**: Logical, if TRUE the `filename` will be forced and existing file with same name will be overwritten.

- **exclude**: Numeric, lines of the model to exclude (see Details).

Details

`write.jags.model` is built upon the function `write.model` of the R2WinBUGS package.

`clean.jags.model` is built upon the function `file.remove`, and intended to be used internally to clean up the JAGS model file after estimating sessions, ideally via the `on.exit` function.

The function `custommodel` can be used to exclude some lines of the model. This is handy when there are variations of the same model. `write.jags.model` accepts results returned by `custommodel`. This is also the preferred way of including BUGS models into R packages, because the function form often includes undefined functions.

Use the %% operator if the model is a function and the model contains truncation (I() in WinBUGS, T() in JAGS). See explanation on help page of `write.model`.

Value

- `write.jags.model` invisibly returns the name of the file that was written eventually (possibly including random string).
- `clean.jags.model` invisibly returns the result of `file.remove` (logical). Original working directory is restored.
- `custommodel` returns an object of class 'custommodel', which is a character vector.

Author(s)

Peter Solymos, <solymos@ualberta.ca>
