Package ‘effects’

February 19, 2015

Version 3.0-3
Date 2014/12/09
Title Effect Displays for Linear, Generalized Linear, and Other Models
Suggests nlme, MASS, poLCA, heplots, splines
Imports pbkrtest, lme4, nnet, lattice, grid, colorspace
LazyLoad yes
LazyData yes
Description Graphical and tabular effect displays, e.g., of interactions, for various statistical models with linear predictors.
License GPL (>= 2)

Author John Fox [aut, cre], Sanford Weisberg [aut], Michael Friendly [aut], Jangman Hong [aut], Robert Andersen [ctb], David Firth [ctb], Steve Taylor [ctb]

Maintainer John Fox <jfox@mcmaster.ca>

**Description**

Graphical and tabular effect displays, e.g., of interactions, for linear (including fit via `gls`), multivariate-linear, generalized linear, multinomial-logit, proportional-odds logit, mixed-effect, polytomous latent-class, and some other models; (multidimensional) component+residual plots for linear and generalized linear models.

**Details**

- Package: effects
- Version: 3.0-3
- Date: 2014/12/09
- Depends: lattice, grid, colorspace
- Suggests: nlme, lme4, MASS, nnet, poLCA
- LazyLoad: yes
- LazyData: yes
- License: GPL (>= 2)
- URL: http://www.r-project.org, http://socserv.socsci.mcmaster.ca/jfox/

This package creates effect displays for various kinds of models, as partly explained in the references. Typical usage is `plot(allEffects(model))`, where `model` is an appropriate fitted-model object. Additional arguments to `allEffects` and `plot` can be used to customize the resulting displays. The function `effect` can be employed to produce an effect display for a particular term in the model, or to which terms in the model are marginal. The function `Effect` may similarly be used to produce an effect display for any combination of predictors. For linear and generalized linear models it is also possible to plot partial residuals to obtain (multidimensional) component+residual
plots. See `effect`, `Effect`, and `plot.eff` for details.

**Author(s)**

John Fox <jfox@mcmaster.ca>, Sanford Weisberg, Michael Friendly, and Jangman Hong. We are grateful to Robert Andersen, David Firth, and for various suggestions.

<table>
<thead>
<tr>
<th>Arrests</th>
<th>Arrests for Marijuana Possession</th>
</tr>
</thead>
</table>

**Description**

Data on police treatment of individuals arrested in Toronto for simple possession of small quantities of marijuana. The data are part of a larger data set featured in a series of articles in the Toronto Star newspaper.

**Usage**

*Arrests*

**Format**

A data frame with 5226 observations on the following 8 variables.

- **released** Whether or not the arrestee was released with a summons; a factor with levels: No; Yes.
- **colour** The arrestee’s race; a factor with levels: Black; White.
- **year** 1997 through 2002; a numeric vector.
- **age** in years; a numeric vector.
- **sex** a factor with levels: Female; Male.
- **employed** a factor with levels: No; Yes.
- **citizen** a factor with levels: No; Yes.
- **checks** Number of police data bases (of previous arrests, previous convictions, parole status, etc. – 6 in all) on which the arrestee’s name appeared; a numeric vector

BEPS  

British Election Panel Study

Description

These data are drawn from the 1997-2001 British Election Panel Study (BEPS).

Usage

BEPS

Format

A data frame with 1525 observations on the following 10 variables.

vote  Party choice: Conservative, Labour, or Liberal Democrat
age  in years
economic.cond.national  Assessment of current national economic conditions, 1 to 5.
economic.cond.household  Assessment of current household economic conditions, 1 to 5.
Blair  Assessment of the Labour leader, 1 to 5.
Hague  Assessment of the Conservative leader, 1 to 5.
Kennedy  Assessment of the leader of the Liberal Democrats, 1 to 5.
Europe  an 11-point scale that measures respondents’ attitudes toward European integration. High scores represent ‘Eurosceptic’ sentiment.
political.knowledge  Knowledge of parties’ positions on European integration, 0 to 3.
gender  female or male.

Cowles

Cowles and Davis’s Data on Volunteering

Description

The Cowles data frame has 1421 rows and 4 columns. These data come from a study of the personality determinants of volunteering for psychological research.

Usage

Cowles

Format

This data frame contains the following columns:

- **neuroticism** scale from Eysenck personality inventory.
- **extraversion** scale from Eysenck personality inventory.
- **sex** a factor with levels: female; male.
- **volunteer** volunteeing, a factor with levels: no; yes.

**Functions For Constructing Effect Plots**

**Description**

`effect` constructs an "eff" object for a term (usually a high-order term) in a linear (fit by `lm` or `gls`) or generalized linear model (fit by `glm`), or an "effpoly" object for a term in a multinomial or proportional-odds logit model (fit respectively by `multinom` or `polr`), absorbing the lower-order terms marginal to the term in question, and averaging over other terms in the model. For multivariate linear models (`mlm`), the function constructs a list of "eff" objects separately for the various response variables.

The function can also be used with mixed-effects models fit with `lmer` from the `lme4` package, or fit with `lme` from the `nlme` package, and for polytomous latent-class models fit by the `polca` function in the `poLCA` package. In mixed effects models the analysis is for the fixed effects only, not for random effects. The `effect` function works by constructing a call to `Effect`. `effect` also constructs an an "eff" object, but rather than focusing on a term in the model, it focuses on a subset of the predictors. `effect` is consequently more flexible and robust than `effect`, and will work with some models for which `effect` fails, such as models with nested terms (see the examples). The `effect` function calls `Effect`. There is a default method for `Effect` that should work with any model object that has a linear predictor and responds to the `coef`, `model.frame`, `formula`, and `vcov` functions.

`allEffects` identifies all of the high-order terms in a model and returns a list of "eff" or "effpoly" objects (i.e., an object of type "efflist").

**Usage**

```r
effect(term, mod, vcov.=vcov, ...)

Effect(focal.predictors, mod, ...)
```

```r
## S3 method for class 'lm'
Effect(focal.predictors, mod, xlevels = list(), default.levels = NULL, given.values, vcov.=vcov, se = TRUE, confidence.level = 0.95, transformation = list(link = family(mod)$linkfun, inverse = family(mod)$linkinv), typical = mean, offset = mean, partial.residuals=FALSE, quantiles=seq(0.2, 0.8, by=0.2), x.var=NULL, ...)
```

```r
## S3 method for class 'gls'
Effect(focal.predictors, mod, xlevels = list(), default.levels=NULL, given.values, vcov.=vcov, se = TRUE, confidence.level = 0.95, transformation = NULL, typical = mean, ...)
```

```r
## S3 method for class 'multinom'
Effect(focal.predictors, mod, confidence.level=.95, xlevels=list(), default.levels=NULL,
```
## S3 method for class 'polr'

```r
effect(focal.predictors, mod,
    confidence.level=.95, xlevels=list(), default.levels=NULL,
    given.values, vcov.=vcov, se=TRUE, typical=mean, ...
)
```

## S3 method for class 'mer'

```r
effect(focal.predictors, mod,
    KR=require("pbkrtest", quietly=TRUE), ...
)
```

## S3 method for class 'merMod'

```r
effect(focal.predictors, mod,
    KR=require("pbkrtest", quietly=TRUE), ...
)
```

## S3 method for class 'lme'

```r
effect(focal.predictors, mod, ...) 
```

## S3 method for class 'poLCA'

```r
effect(focal.predictors, mod, ...) 
```

## S3 method for class 'mlm'

```r
effect(focal.predictors, mod, response, ...) 
```

## Default S3 method:

```r
effect(focal.predictors, mod, xlevels = list(),
    default.levels = NULL, given.values, 
    vcov. = vcov, se = TRUE, confidence.level = 0.95,
    transformation = list(link = I, inverse = I),
    typical = mean, offset = mean, ...
)
```

allEffects(mod, ...) 

## S3 method for class 'mer'

```r
allEffects(mod, ...) 
```

## S3 method for class 'merMod'

```r
allEffects(mod, ...) 
```

## S3 method for class 'lme'

```r
allEffects(mod, ...) 
```

## S3 method for class 'poLCA'

```r
allEffects(mod, ...) 
```

## S3 method for class 'eff'

```r
as.data.frame(x, row.names=NULL, optional=TRUE,
    transform=x$transformation$inverse, ...) 
```
Arguments

term
the quoted name of a term, usually, but not necessarily, a high-order term in the model. The term must be given exactly as it appears in the printed model, although either colons (:) or asterisks (*) may be used for interactions.

focal.predictors
a character vector of one or more predictors in the model.

mod
an object of class "lm", "gls", "glm", "multinom", "polr", "mer" (or "merMod"), "lme" or "polca".

xlevels
this argument is used to set the number of levels for any focal predictor that is not a factor. If xlevels=NULL, the default, then the number and values of levels for any numeric predictor is determined by grid.pretty. If xlevels=n is an integer, then each numeric predictor is represented by n equally spaced levels. More generally, xlevels can be a named list of values at which to set each numeric predictor. For example, xlevels=list(x1=c(2, 4, 7), x2=5) would use the values 2, 4 and 7 for the levels of x1, 5 equally spaced levels for the levels of x2, and use the default for any other numeric predictors. If partial residuals are computed, then the focal predictor that is to appear on the horizontal axis of an effect plot is evaluated at 100 equally spaced values along its full range, and, by default, other numeric predictors are evaluated at the quantiles specified in the quantiles argument, unless their values are given explicitly in xlevels.

default.levels
ignored, but included for compatibility with pre-July 2013 versions of this package. Use xlevels instead.

given.values
a numeric vector of named elements, setting particular columns of the model matrix to specific values for predictors that are not focal predictors; if specified, this argument takes precedence over the application of the function given in the typical argument (below). Care must be taken in specifying these values — e.g., for a factor, the values of all contrasts should be given and these should be consistent with each other.

vcov
A function or the name of a function that will be used to get the estimated variance covariance matrix of the estimated coefficients. This will ordinarily be the default, vcov, which will result in the function call vcov(mod) to get the variance covariance matrix. You can use the name of any function with mod as the value of its first argument that returns an estimated sample covariance matrix, such as the hccm function in the car package that returns a heteroscedasticity corrected estimate with linear models.
if TRUE, the default, calculate standard errors and confidence limits for the effects. For mer, merMod, and lme objects, the normal distribution is used to get confidence limits.

level at which to compute confidence limits based on the standard-normal distribution; the default is 0.95.

if TRUE, the default if the pbkrtest package is installed, use the Kenward-Roger coefficient covariance matrix to compute effect standard errors for linear mixed models fit with lmer in the lme4 package.

a two-element list with elements link and inverse. For a generalized linear model, these are by default the link function and inverse-link (mean) function. For a linear model, these default to NULL. If NULL, the identify function, I, is used; this effect can also be achieved by setting the argument to NULL. The inverse-link may be used to transform effects when they are printed or plotted; the link may be used in positioning axis labels (see below). If the link is not given, an attempt will be made to approximate it from the inverse-link.

a function to be applied to the columns of the model matrix over which the effect is "averaged"; the default is mean.

a function to be applied to the offset values (if there is an offset) in a linear or generalized linear model, or a mixed-effects model fit by lmer or glmer; or a numeric value, to which the offset will be set. The default is the mean function, and thus the offset will be set to its mean. Note: Only offsets defined by the offset argument to lm, glm, lmer, or glmer will be handled correctly; use of the offset function in the model formula is not supported.

if TRUE, partial residuals will be computed for an effect in a linear or generalized linear model; if FALSE (the default), partial residuals are suppressed.

quantiles at which to evaluate numeric focal predictors not on the horizontal axis, used only when partial residuals are displayed; superceded if the xlevels argument gives specific values for a predictor.

the name or index of the numeric predictor to define the horizontal axis of an effect plot for a linear or generalized linear model; the default is NULL, in which case the first numeric predictor in the effect will be used if partial residuals are to be computed. This argument is intended to be used when partial.residuals is TRUE; otherwise, the variable on the horizontal axis can be chosen when the effect object is plotted: see plot eff.

if TRUE, effects in a proportional-odds logit model are computed on the scale of the latent response; if FALSE (the default) effects are computed as individual-level probabilities and logits.

an object of class "eff", "effpoly", or "efflatent".

a transformation to be applied to the effects and confidence limits, by default taken from the inverse link function saved in the "eff" object.

not used.

for an mlm, a vector containing the name(s) or indices of one or more response variable(s). The default is to use all responses in the model.
effect

object an object of class "eff" for which the covariance matrix of the effects is desired.

... arguments to be passed down.

Details

Normally, the functions to be used directly are allEffects, to return a list of high-order effects, and the generic plot function to plot the effects. (see plot.efflist, plot.eff, and plot.effpoly). Alternatively, Effect can be used to vary a subset of predictors over their ranges, while other predictors are held to typical values. Plots are drawn using the xypplot (or in some cases, the densityplot) function in the lattice package. Effects may also be printed (implicitly or explicitly via print) or summarized (using summary) (see print.efflist, summary.efflist, print.eff, summary.eff, print.effpoly, and summary.effpoly).

If asked, the effect function will compute effects for terms that have higher-order relatives in the model, averaging over those terms (which rarely makes sense), or for terms that do not appear in the model but are higher-order relatives of terms that do. For example, for the model $Y \sim A*B + A*C + B*C$, one could compute the effect corresponding to the absent term $A:B:C$, which absorbs the constant, the $A$, $B$, and $C$ main effects, and the three two-way interactions. In either of these cases, a warning is printed.

The as.data.frame methods convert effect objects to data frames to facilitate the construction of custom displays. In the case of "eff" objects, the se element in the data frame is always on the scale of the linear predictor, and the transformation used for the fit and confidence limits is saved in a "transformation" attribute.

Value

For lm, glm, mer and lme, effect and Effect return an "eff" object, and for multinom and polr, an "effpoly" object, with the components listed below. For m1m with one response specified, an "eff" object, otherwise a class "efflist" object, containing one "eff" object for each response.

term the term to which the effect pertains.
formula the complete model formula.
response a character string giving the name of the response variable.
y.levels (for "effpoly" objects) levels of the polytomous response variable.
variables a list with information about each predictor, including its name, whether it is a factor, and its levels or values.
fit (for "eff" objects) a one-column matrix of fitted values, representing the effect on the scale of the linear predictor; this is a ravelled table, representing all combinations of predictor values.
prob (for "effpoly" objects) a matrix giving fitted probabilities for the effect for the various levels of the the response (columns) and combinations of the focal predictors (rows).
logit (for "effpoly" objects) a matrix giving fitted logits for the effect for the various levels of the the response (columns) and combinations of the focal predictors (rows).
x a data frame, the columns of which are the predictors in the effect, and the rows of which give all combinations of values of these predictors.
effect

model.matrix  the model matrix from which the effect was calculated.
data  a data frame with the data on which the fitted model was based.
discrepancy  the percentage discrepancy for the 'safe' predictions of the original fit; should be very close to 0. Note: except for gls models, this is now necessarily 0.
offset  value to which the offset is fixed; 0 if there is no offset.
model  (for "effpoly" objects) "multinom" or "polr", as appropriate.
v cov  (for "eff" objects) a covariance matrix for the effect, on the scale of the linear predictor.
se  (for "eff" objects) a vector of standard errors for the effect, on the scale of the linear predictor.
se.prob, se.logit  (for "effpoly" objects) matrices of standard errors for the effect, on the probability and logit scales.
lower, upper  (for "eff" objects) one-column matrices of confidence limits, on the scale of the linear predictor.
lower.prob, upper.prob, lower.logit, upper.logit  (for "effpoly" objects) matrices of confidence limits for the fitted logits and probabilities; the latter are computed by transforming the former.
confidence.level  for the confidence limits.
transformation  (for "eff" objects) a two-element list, with element link giving the link function, and element inverse giving the inverse-link (mean) function.
fitted.rounded  partial fitted values at the observed values of the predictor x.var and the values of the other predictors that appear in the effect display; predictors not in the effect are held constant to typical values. This and the following two elements are NULL if partial residuals aren't computed and pertain only to linear or generalized linear models.
fitted  partial fitted values for the observed values of all predictors that appear in the effect display; predictors not in the effect are held constant to typical values.
partial.residuals.raw  partial residuals for the effect computed at the actual values of all focal predictors.
partial.residuals.adjusted  partial residuals for the effect computed at the panel-rounded values of focal predictors, except for the predictor corresponding to xvar, which will appear on the horizontal axis of the plotted effect.
x.var  the name of the predictor to appear on the horizontal axis of an effect plot made from the returned object; will usually be NULL if partial residuals aren't computed.

effectList returns a list of "eff" or "effpoly" objects corresponding to the high-order terms of the model.

If mod is of class polCA (from the polCA package) to fit a polytomous latent class model, effects are computed for the predictors given the estimated latent classes. The result is of class eff if the latent class model has 2 categories and of class effpoly with more than 2 categories.
Warnings and Limitations

The `effect` function handles factors and covariates differently, and is likely to be confused if one is changed to the other in a model formula. Consequently, formulas that include calls to `as.factor`, `factor`, or `numeric` (as, e.g., in `y ~ as.factor(income)`) will cause errors. Instead, create the modified variables outside of the model formula (e.g., `fincome <- as.factor(income)`) and use these in the model formula. Similarly variables of class date or "times", which are usually differences between "dates" variables, should be converted to numeric variables outside the model formula.

Factors cannot have colons in level names (e.g., "level:A"); the `effect` function will confuse the colons with interactions; rename levels to remove or replace the colons (e.g., "level.A"). In addition, factors cannot be declared on the fly (e.g., using `y ~ a + factor(b)`).

The functions in the `effects` package work properly with predictors that are numeric or factors; consequently, e.g., convert logical predictors to factors, and dates to numeric.

Empty cells in crossed-factors are now permitted for `lm`, `glm` and `multinom` models.

With multinom models with two or more crossed factors with an empty cell, the 'plot' command with `style="stacked"` apparently does not work because of a bug in the `barchart` function in `lattice`. However, the default `style="lines"` does work.

Offsets in linear and generalized linear models are supported, as are offsets in mixed models fit by `lmer` or `glmer`, but must be supplied through the `offset` argument to `lm`, `glm`, `lmer` or `glmer`; offsets supplied via calls to the `offset` function on the right-hand side of the model formula are not supported.

Calling any of these functions from within a user-written function may result in errors due to R’s scoping rules. See the vignette `embeddingNpdf` for the `car` package for a solution to this problem.

**Description**

The `allEffects` function is provided only for compatibility with older versions of the `effects` package and may be removed; use `allEffects` instead.

**Usage**

`allEffects(...)`

**Arguments**

`...` arguments to be passed to `allEffects`.

**Author(s)**

John Fox <jfox@mcmaster.ca>.

**See Also**

`allEffects`

---

**Hartnagel**

*Canadian Crime-Rates Time Series*

**Description**

The Hartnagel data frame has 38 rows and 7 columns. The data are an annual time-series from 1931 to 1968. There are some missing data.

**Usage**

Hartnagel
Format

This data frame contains the following columns:

- **year**: 1931–1968.
- **tfr**: Total fertility rate per 1000 women.
- **partic**: Women’s labor-force participation rate per 1000.
- **degrees**: Women’s post-secondary degree rate per 10,000.
- **fconvict**: Female indictable-offense conviction rate per 100,000.
- **ftheft**: Female theft conviction rate per 100,000.
- **mconvict**: Male indictable-offense conviction rate per 100,000.
- **mtheft**: Male theft conviction rate per 100,000.

Details

The post-1948 crime rates have been adjusted to account for a difference in method of recording. Some of your results will differ in the last decimal place from those in Table 14.1 of Fox (1997) due to rounding of the data. Missing values for 1950 were interpolated.

<table>
<thead>
<tr>
<th>Prestige</th>
<th>Prestige of Canadian Occupations</th>
</tr>
</thead>
</table>

Description

The Prestige data frame has 102 rows and 6 columns. The observations are occupations.

Usage

Prestige
summary.eff

Format

This data frame contains the following columns:

- **education**: Average education (years) of occupational incumbents, in 1971.
- **income**: Average income (dollars) of incumbents, 1971.
- **women**: Percentage of incumbents who are women, 1971.
- **prestige**: Pineo-Porter prestige score for occupation, from a social survey conducted in the mid-1960s.
- **census**: Canadian Census occupational code.
- **type**: Type of occupation. A factor with levels (note: out of order): **bc**, Blue Collar; **prof**, Professional, Managerial, and Technical; **wc**, White Collar.

## S3 method for class 'efflist'

`x[...]`

### Arguments

- **x**: an object of class "eff", "effpoly", "efflist", "mlm.efflist", or "summary.eff", as appropriate.
object: an object of class "eff", "effpoly", "efflist", or "mlm.efflist", as appropriate.

type: for linear and generalized linear models, if "response" (the default), effects are printed or the vertical axis is labelled on the scale of the response variable; if "link", effects are printed or the vertical axis labelled on the scale of the linear predictor. For polytomous logit models, this argument takes either "probability" or "logit", with the former as the default.

x.var: the index (number) or quoted name of the covariate or factor to place on the horizontal axis of each panel of the effect plot. The default is the predictor with the largest number of levels or values.

z.var: for linear, generalized linear or mixed models, the index (number) or quoted name of the covariate or factor for which individual lines are to be drawn in each panel of the effect plot. The default is the predictor with the smallest number of levels or values. This argument is only used if multiline = TRUE.

multiline: for linear, generalized linear or mixed models, if TRUE, each panel of the display represents combinations of values of two predictors, with one predictor (corresponding to x.var) on the horizontal axis, and the other (corresponding to z.var) used to define lines in the graph; defaults to TRUE if there are no standard errors in the object being plotted, and FALSE otherwise.

confint: plot point-wise confidence bands around fitted effects (for multinomial and proportional-odds logit models); defaults to TRUE, in which case separate panels are used for different response levels.

rug: if TRUE, the default, a rug plot is shown giving the marginal distribution of the predictor on the horizontal axis, if this predictor is a covariate. The rug plot is suppressed if partial residuals are plotted.

xlab: the label for the horizontal axis of the effect plot; if missing, the function will use the name of the predictor on the horizontal axis.

ylab: the label for the vertical axis of the effect plot; the default is constructed from the name of the response variable for the model from which the effect was computed.

main: the title for the plot, printed at the top; the default title is constructed from the name of the effect.

colors: colors[1] is used to plot effects, colors[2] to plot confidence limits when ci.style is not equal to "bands". In a multiline plot, the successive colors correspond to the levels of the z.var covariate or factor. In a stacked plot or a plot without confidence bands for a multinomial or proportional-odds logit model, the successive colors correspond to the levels of the response factor. In all but stacked plots, colors defaults to palette(). If colors is shorter than the number of levels, then it is recycled, so colors="black" will use black for all levels.

For stacked multinomial-logit plots, colors defaults to rainbow_hcl(levels), where levels is the number of levels of the response variable; for stacked proportional-odds model plots, colors defaults to sequential_hcl(levels). colors does not recycle for stacked plots.

Warning: This argument cannot be abbreviated to col, which is used for a different purpose (see below).
symbols, lines corresponding to the levels of the z.var covariate or factor on a multiline plot, or to the successive levels of the response factor in a line plot for a polytomous logit model. These arguments are used only if multiline = TRUE or for polytomous logit models where the effects are plotted without confidence bands; in these cases a legend is drawn at the top of the display. If these arguments are too short they are recycled.

cex character expansion for plotted symbols; default is 1.5.
lwd line width for fitted lines
ylim 2-element vector containing the lower and upper limits of the vertical axes; if NULL, the default, then the vertical axes are scaled from the data.
xlim a named list of 2-element vectors, with the names corresponding to numeric predictors; if a numeric predictor is in the list, then when it appears on the horizontal axis, the axis limits will be taken from the corresponding vector; if a predictor is not in the list, or if the argument is NULL (the default), then the horizontal axis limits are computed from the data.
factor.names a logical value, default TRUE, that controls the inclusion of factor names in conditioning-variable labels.
ci.style confidence bounds can be indicated using error bars, using lines or confidence bands, depending on the plot type. For single line plots the default is "bars" for factors and "bands" for variates. Style "lines" can also be used for either of these. For multiline plots, the default is "none" for no confidence bounds, but style "bars" or "bands" can also be used. For a variate the option "bars" displays the error bars at each of the levels points for which the horizontal variable was evaluated.
band.colors A vector of colors for the color of the confidence band with ci.style="bands". The default is band.colors=colors. For plots with one line, the choice, setting band.colors="red" produces a pleasing result, even if color provides no additional information in this case. If this argument is too short it is recycled.
band.transparency
For ci.style="bands", the alpha transparency of the fill color. Not all graphic devices support transparency.

style (for multinomial or proportional-odds logit models) "lines" (the default for a line plot, or "stacked" for a stacked-bar or stacked-area plot. In the latter case only fitted probabilities may be plotted and confidence envelopes cannot be shown.
ticks a two-item list controlling the placement of tick marks on the vertical axis, with elements at and n. If at=NULL (the default), the program attempts to find ‘nice’ locations for the ticks, and the value of n (default, 5) gives the approximate number of tick marks desired; if at is non-NULL, then the value of n is ignored.
ticks.x a named list of two-item lists controlling the placement of tick marks on the horizontal axis. Each list element is named for a numeric predictor in the model, and each sublist has elements at or n are for the ticks argument. If a predictor doesn’t appear in the list, or if ticks.x is NULL (the default), then the tick marks are computed by the function.
transform.x transformations to be applied to the horizontal axis, in the form of a named list, each of whose elements is itself a list of two functions, with sublist element names trans and inverse. The names of the list elements are numeric predictors in the model whose axes are to be transformed; the trans function is applied to the values of the predictor, and inverse is used for computing proper axis tick labels. If a numeric predictor is missing from transform.x then its axis is not transformed; if the argument is NULL (the default), then no predictor axes are transformed.

alternating if TRUE (the default), the tick labels alternate by panels in multi-panel displays from left to right and top to bottom; if FALSE, tick labels appear at the bottom and on the left.

rotx, roty rotation angles for the horizontal and vertical tick marks, respectively. Default is 0.

grid if TRUE, add grid lines to the plot. Default is FALSE.

layout the layout argument to the lattice function xyplot (or, in some cases densityplot), which is used to draw the effect display; if not specified, the plot will be formatted so that it appears on a single page.

rescale.axis if TRUE (the default), the tick marks on the vertical axis are labelled on the response scale (e.g., the probability scale for effects computed on the logit scale for a binomial GLM).

key.args additional arguments to be passed to the key trellis argument to xyplot or densityplot, e.g., to position the key (legend) in the plotting region; may also be used to modify the default behavior of the key.

row, col, nrow, ncol, more

These arguments are used to graph an effect as part of an array of plots; row, col, nrow, and ncol are used to compose the split argument and more the more argument to print.trellis. Normally these arguments are not set by the user, but by plot.efflist. Warning: Note that col is not used to specify colors; use colors instead (see above).

selection the optional index (number) or quoted name of the effect in an effect list to be plotted; if not supplied, a menu of high-order terms is presented or all effects are plotted.

rows, cols Number of rows and columns in the “meta-array” of plots produced for an efflist object; if either argument is missing, then the meta-layout will be computed by the plot method.

ask if selection is not supplied and ask is TRUE, a menu of high-order terms is presented; if ask is FALSE (the default), effects for all high-order terms are plotted in an array.

graphics if TRUE (the default), then the menu of terms to plot is presented in a dialog box rather than as a text menu.

use.splines If TRUE, the default, then any lines drawn when the horizontal axis is not a factor use interpolating splines computed by the spline function. If FALSE, then linear interpolation is used. This argument is ignored if the horizontal axis is a factor.
partial.residuals
use "adjusted" partial residuals, computed at the panel-rounded values of the focal predictors not on the horizontal axis of each panel, or "raw" partial residuals, computed at the actual values of all focal predictors; the default is "adjusted", and this argument is effective only when partial residuals are included in the effect object to be plotted — see Effect.

smooth.residuals
whether to show a loess smooth of the partial residuals, if they are present; the default is TRUE.

span
of the xypolot smoother to be applied to partial residuals; the default is 2/3.

show.fitted
if partial residuals are present in the effect object, also plot the partial fitted values (which will be shown as filled circles).

residuals.color
color for plotting partial residuals (default "blue").

residuals.pch
plotting symbol for partial residuals (default 1, open circles).

... arguments to be passed down.

Details
In a generalized linear model, by default, the print and summary methods for eff objects print the computed effects on the scale of the response variable using the inverse of the link function. In a logit model, for example, this means that the effects are expressed on the probability scale.

By default, effects in a GLM are plotted on the scale of the linear predictor, but the vertical axis is labelled on the response scale. This preserves the linear structure of the model while permitting interpretation on what is usually a more familiar scale. This approach may also be used with linear models, for example to display effects on the scale of the response even if the data are analyzed on a transformed scale, such as log or square-root.

In a polytomous (multinomial or proportional-odds) logit model, by default effects are plotted on the probability scale; they may be alternatively plotted on the scale of the individual-level logits.

Value
The summary method for "eff" objects returns a "summary.eff" object with the following components (those pertaining to confidence limits need not be present):

header
a character string to label the effect.

effect
an array containing the estimated effect.

lower.header
a character string to label the lower confidence limits.

lower
an array containing the lower confidence limits.

upper.header
a character string to label the upper confidence limits.

upper
an array containing the upper confidence limits.

The [ method for "efflist" objects is used to subset an "efflist" object and returns an object of the same class.

**TitanicSurvival**  **Survival of Passengers on the Titanic**

**Description**

Information on the survival status, sex, age, and passenger class of 1309 passengers in the Titanic disaster of 1912.

**Usage**

TitanicSurvival

**Format**

A data frame with 1309 observations on the following 4 variables.

survived  no or yes.
sex  female or male
age  in years (and for some children, fractions of a year); age is missing for 263 of the passengers.
passengerClass  1st, 2nd, or 3rd class.
Details
This is part of a larger data set compiled by Thomas Cason. Many additional details are given in the sources cited below.

Source

---

Description
Data on whether or not households in Bangladesh changed the wells that they were using.

Usage
Wells

Format
A data frame with 3020 observations on the following 5 variables.

  switch  whether or not the household switched to another well from an unsafe well: no or yes.
  arsenic the level of arsenic contamination in the household’s original well, in hundreds of micrograms per liter; all are above 0.5, which was the level identified as “safe”.
  distance in meters to the closest known safe well.
education in years of the head of the household.
association whether or not any members of the household participated in any community organizations: no or yes.

Details
The data are for an area of Arahazar upazila, Bangladesh. The researchers labelled each well with its level of arsenic and an indication of whether the well was “safe” or “unsafe.” Those using unsafe wells were encouraged to switch. After several years, it was determined whether each household using an unsafe well had changed its well. These data are used by Gelman and Hill (2007) for a logistic-regression example.
