Package ‘ggvis’

March 12, 2015

Title Interactive Grammar of Graphics

Description An implementation of an interactive grammar of graphics, taking the best parts of ggplot2, combining them with shiny’s reactive framework and drawing web graphics using vega.

Version 0.4.1

URL http://ggvis.rstudio.com/

Depends R (>= 3.0)

Imports assertthat, jsonlite (>= 0.9.11), shiny (>= 0.11.1), magrittr, dplyr (>= 0.3), lazyeval, htmltools (>= 0.2.4)

Suggests MASS, mgcv, lubridate, testthat (>= 0.8.1), knitr (>= 1.6), rmarkdown

VignetteBuilder knitr

License GPL-2 | file LICENSE

LazyData true

**add_axis**

Add a vega axis specification to a ggvis plot

**Description**

Axis specifications allow you to either override the default axes, or additional axes.

**Usage**

```r
add_axis(vis, type, scale = NULL, orient = NULL, title = NULL,
          title_offset = NULL, format = NULL, ticks = NULL, values = NULL,
          subdivide = NULL, tick_padding = NULL, tick_size_major = NULL,
          tick_size_minor = tick_size_major, tick_size_end = tick_size_major,
          offset = NULL, layer = "back", grid = TRUE, properties = NULL)
```

```r
hide_axis(vis, scale)
```
Arguments

vis A ggvis object.
type The type of axis. Either x or y.
scale The name of the scale backing the axis component. Defaults to the scale type - you will need to specify if you want (e.g.) a scale for a secondary y-axis.
orient The orientation of the axis. One of top, bottom, left or right. The orientation can be used to further specialize the axis type (e.g., a y axis oriented for the right edge of the chart) - defaults to bottom for x axes, and left for y axes.
title A title for the axis. By default, it uses the name of the field in the first data set used by the scale. Use "" to suppress the title.
title_offset The offset (in pixels) from the axis at which to place the title.
format The formatting pattern for axis labels. Vega uses D3's format pattern: https://github.com/mbostock/d3/wiki/Formatting
ticks A desired number of ticks. The resulting number may be different so that values are "nice" (multiples of 2, 5, 10) and lie within the underlying scale's range.
values Explicitly set the visible axis tick values.
subdivide If provided, sets the number of minor ticks between major ticks (the value 9 results in decimal subdivision).
tick_padding The padding, in pixels, between ticks and text labels.
tick_size_major,tick_size_minor,tick_size_end The size, in pixels, of major, minor and end ticks.
offset The offset, in pixels, by which to displace the axis from the edge of the enclosing group or data rectangle.
layer A string indicating if the axis (and any gridlines) should be placed above or below the data marks. One of "front" or "back" (default).
grid A flag indicating if gridlines should be created in addition to ticks.
properties Optional mark property definitions for custom axis styling. Should be an object created by axis_props, with properties for ticks, majorTicks, minorTicks, grid, labels, title, and axis.

Details

More information about axes can be found in the "axes and legends" vignettes.

Compared to ggplot2

In ggplot2, axis (and legend) properties are part of the scales specification. In vega, they are separate, which allows the specification of multiple axes, and more flexible linkage between scales and axes.

See Also

Vega axis documentation: https://github.com/trifacta/vega/wiki/Axes
**Examples**

```r
mtcars %>% ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
  add_axis("x", title = "Weight", orient = "top")

# Suppress axis with hide_axis
mtcars %>% ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
  hide_axis("x") %>% hide_axis("y")

mtcars %>% ggvis(x = ~wt, y = ~mpg) %>%
  layer_points() %>%
  add_axis("x", title = "Weight", ticks = 40,
  properties = axis Props(
    ticks = list(stroke = "red"),
    majorTicks = list(strokeWidth = 2),
    grid = list(stroke = "red"),
    labels = list(
      fill = "steelblue",
      angle = 50,
      fontSize = 14,
      align = "left",
      baseline = "middle",
      dx = 3
    ),
    title = list(fontSize = 16),
    axis = list(stroke = "+333", strokeWidth = 1.5)
  ))
```

---

**add_data**

*Add dataset to a visualisation*

**Description**

Add dataset to a visualisation

**Usage**

```r
add_data(vis, data, name = deparse2(substitute(data)), add_suffix = TRUE)
```

**Arguments**

- **vis**
  Visualisation to modify.
- **data**
  Data set to add.
- **name**
  Data of data - optional, but helps produce informative error messages.
- **add_suffix**
  Should a unique suffix be added to the data object’s ID? This should only be
  FALSE when the spec requires a data set with a specific name.
Examples

```r
mtcars %>% ggvis(~mpg, ~wt) %>% layer_points()
NULL %>% ggvis(~mpg, ~wt) %>% add_data(mtcars) %>% layer_points()
```

---

**add_guide_axis**  
*Defunct function for adding an axis*

### Description

This function has been replaced with `add_axis`.

### Usage

```r
add_guide_axis(...)```

### Arguments

... Other arguments.

---

**add_guide_legend**  
*Defunct function for adding a legend*

### Description

This function has been replaced with `add_legend`.

### Usage

```r
add_guide_legend(...)```

### Arguments

... Other arguments.
add_legend

Add a vega legend specification to a ggvis plot

Description

Axis specifications allow you to either override the default legends, or supply additional legends.

Usage

add_legend(vis, scales = NULL, orient = "right", title = NULL,
            format = NULL, values = NULL, properties = NULL)

hide_legend(vis, scales)

Arguments

vis
A ggvis object.

scales
The name of one or more scales for which to add a legend. Typically one of "size", "shape", "fill", "stroke", although custom scale names may also be used. Multiple names can also be used, like c("fill", "shape").

orient
The orientation of the legend. One of "left" or "right". This determines how the legend is positioned within the scene. The default is "right".

title
A title for the legend. By default, it uses the name the fields used in the legend. Use "" to suppress the title.

format
The formatting pattern for axis labels. Vega uses D3’s format pattern: https://github.com/mbostock/d3/wiki/Formatting

values
Explicitly set the visible legend values.

properties
Optional mark property definitions for custom legend styling. Should be an object created by legend_props, with properties for title, label, symbols, gradient, legend.

Details

More information about axes can be found in the "axes and legends" vignettes.

Compared to ggplot2

In ggplot2, legend (and axis) properties are part of the scales specification. In vega, they are separate, which allows the specification of multiple legends, and more flexible linkage between scales and legends.
Examples

```r
mtcars %> ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
  add_legend("fill", title = "Cylinders")

# Suppress legend with hide_legend
mtcars %> ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
  hide_legend("fill")

# Combining two properties in one legend
mtcars %>%
ggvis(x = ~wt, y = ~mpg, fill = ~factor(cyl), shape = ~factor(cyl)) %>%
  layer_points() %>%
  add_legend(c("fill", "shape"))

# Control legend properties with a continuous legend, with x and y position
# in pixels.
mtcars %>% ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
  add_legend("fill", title = "Cylinders",
  properties = legend_props(
    title = list(fontSize = 16),
    labels = list(fontSize = 12, fill = "#00F"),
    gradient = list(stroke = "red", strokeWidth = 2),
    legend = list(x = 500, y = 50)
  )
)

# Control legend properties with a categorical legend, with x and y position
# in the scaled data space.
mtcars %>% ggvis(x = ~wt, y = ~mpg, fill = ~factor(cyl)) %>%
  layer_points() %>%
  add_legend("fill", title = "Cylinders",
  properties = legend_props(
    title = list(fontSize = 16),
    labels = list(fontSize = 14, dx = 5),
    symbol = list(stroke = "black", strokeWidth = 2,
      shape = "square", size = 200),
    legend = list(
      x = scaled_value("x", 4.5),
      y = scaled_value("y", 30)
    )
  )
)

# Control legend position using x_rel and y_rel which specify relative
# position, going from 0 to 1. (0, 0) is the bottom-left corner, and
# (1, 1) is the upper-right corner. The values control the position of
# the upper-left corner of the legend.
mtcars %>% ggvis(x = ~wt, y = ~mpg, fill = ~cyl) %>%
  layer_points() %>%
```
add_props

```r
add_relative_scales()
add_legend("fill", title = "Cylinders",
  properties = legend_props(
    legend = list(
      x = scaled_value("x_rel", 0.8),
      y = scaled_value("y_rel", 1)
    )
  )
)
```

---

**add_props**  
*Add visual properties to a visualisation*

**Description**

Add visual properties to a visualisation

**Usage**

```r
add_props(vis, ..., .props = NULL, inherit = NULL, env = parent.frame())
```

**Arguments**

- `vis`: Visualisation to modify.
- `...`: A set of name-value pairs. The name should be a valid vega property. The first two unnamed components are taken to be `x` and `y`. Any additional unnamed components will raise an error.
- `.props`: When calling `props` from other functions, you’ll often have a list of quoted function functions. You can pass that function to the `.props` argument instead of messing around with `substitute`. In other words, `.props` lets you opt out of the non-standard evaluation that `props` does.
- `inhibit`: If TRUE, the defaults, will inherit from properties from the parent layer. If FALSE, it will start from nothing.
- `env`: The environment in which to evaluate variable properties.

**Examples**

```r
mtcars %>% ggvis(~wt, ~mpg) %>% layer_points()
mtcars %>% ggvis() %>% add_props(~wt, ~mpg) %>% layer_points()
mtcars %>% ggvis(~wt) %>% add_props(y = ~mpg) %>% layer_points()
```
add_relative_scales  Add x_rel and y_rel scales

Description

This function adds scales named x_rel and y_rel, each of which has a domain of 0 to 1, and the range is the plot’s width or height. These scales are useful for positioning visual elements relative to the plotting area. For example, with legends.

Usage

add_relative_scales(vis)

Arguments

vis A ggvis object.

See Also

add_legend for a usage example.

add_tooltip  Add tooltips to a plot.

Description

Add tooltips to a plot.

Usage

add_tooltip(vis, html, on = c("hover", "click"))

Arguments

vis Visualisation to add tooltips to.

html A function that takes a single argument as input. This argument will be a list containing the data in the mark currently under the mouse. It should return a string containing HTML or NULL to hide tooltip for the current element.

on Should tooltips appear on hover, or on click?
Examples

```r
all_values <- function(x) {
  if(is.null(x)) return(NULL)
  paste0(names(x), ": ", format(x), collapse = "<br/>")
}

base <- mtcars %>% ggvis(~wt, y = ~mpg) %>%
    layer_points()
base %>% add_tooltip(all_values, "hover")
base %>% add_tooltip(all_values, "click")

# The data sent from client to the server contains only the data columns that
# are used in the plot. If you want to get other columns of data, you should
# to use a key to line up the item from the plot with a row in the data.

mtc <- mtcars
mtc$id <- 1:nrow(mtc) # Add an id column to use ask the key

all_values <- function(x) {
  if(is.null(x)) return(NULL)
  row <- mtc[mtc$id == x$id,]
  paste0(names(row), ": ", format(row), collapse = "<br/>")
}

mtc %>% ggvis(~wt, y = ~mpg, key := ~id) %>%
    layer_points() %>%
    add_tooltip(all_values, "hover")
```

---

auto_group

Automatically group data by grouping variables

Description

Use `auto_group` to group up a dataset on all categorical variables specified by `props`, and have each piece rendered by the same mark.

Usage

```r
auto_group(vis, exclude = NULL)
```

Arguments

- **vis** The `ggvis` visualisation to modify.
- **exclude** A vector containing names of props to exclude from auto grouping. It is often useful to exclude `c("x", "y")`, when one of those variables is categorical.
See Also

To manually specify grouping variables, see `group_by`.

Examples

```r
# One line
mtcars %>% ggvis(~disp, ~mpg, stroke = ~factor(cyl)) %>% layer_paths()
# One line for each level of cyl
mtcars %>% ggvis(~disp, ~mpg, stroke = ~factor(cyl)) %>% group_by(cyl) %>%
    layer_paths()
mtcars %>% ggvis(~disp, ~mpg, stroke = ~factor(cyl)) %>% auto_group() %>%
    layer_paths()

# The grouping column can already be stored as a factor
mtcars2 <- mtcars
mtcars2$cyl <- factor(mtcars2$cyl)
mtcars2 %>% ggvis(~disp, ~mpg, stroke = ~cyl) %>% auto_group() %>%
    layer_paths()
```

---

### axis_props

Create an axis_props object for controlling axis properties.

#### Description

The items in each of the lists can be a literal value, like 5 or "blue", or they can be a `scaled_value` object.

#### Usage

```r
axis_props(ticks = NULL, majorTicks = NULL, minorTicks = NULL,
          grid = NULL, labels = NULL, title = NULL, axis = NULL)
```

#### Arguments

- `ticks`: A named list of line properties for ticks.
- `majorTicks`: A named list of line properties for major ticks.
- `minorTicks`: A named list of line properties for minor ticks.
- `grid`: A named list of line properties for grid lines.
- `labels`: A named list of text properties for axis labels.
- `title`: A named list of text properties for the axis title.
- `axis`: A named list of line properties for the axis line.
**band**

| band | A band |

**Description**

Bands are used to set the width or height on categorical scales - a band represent the height or width allocated for one level of a factor.

**Usage**

```r
band(offset = NULL, mult = NULL)
```

```r
is.prop_band(x)
```

**Arguments**

- `offset`, `mult` Additive and multiplicate offsets used to adjust the band size. For example, use `mult = 0.9` to make a bar take up 90% of the space allocated for its category.
- `x` object to test for band-ness

**Examples**

```r
df <- data.frame(label = c("a", "b", "c"), n = c(10, 9, 4))

base <- df %>% ggvis(~label, y = ~y, y = ~n)
base %>% layer_rects(width = band())
base %>% layer_rects(width = band(offset = -1))
base %>% layer_rects(width = band(mult = 0.9))

# A nominal scale with padding is more symmetrical than band with a mult
base %>% layer_rects(width = band(mult = 0.75))
base %>% layer_rects(width = band(mult = 0.75)) %>%
  scale_nominal("x", padding = 0.25, points = FALSE)
```

---

**cocaine**

*Cocaine seizures in the US.*

| cocaine |

**Description**

This dataset comes from STRIDE, the System to Retrieve Information from Drug Evidence. It contains all cocaine seizures in the US from 2007 that have a known weight.

**Usage**

```r
cocaine
```
compute_align

Format
Data frame with 3380 observations of 5 variables.

Variables
- **state**: State where seizure occurred.
- **potency**: Purity of cocaine, as percentage (100% = pure cocaine, 0% = all filler)
- **weight**: Weight, in grams.
- **month**: Month in which seizure occurred.
- **price**: Estimated value in USD.

Use
Use of this data requires your agreement to refer to your analyses as "unvalidated DEA data and to
claim authorship and responsibility for any inferences and/or conclusions you may draw from this
information."

Source

compute_align  
Align positions using length.

Description
This compute function is often used in conjunction with compute_count, when used on data with
a continuous x variable. By default, the computed width will be equal to the resolution of the data,
or, in other words the smallest difference between two values in the data.

Usage
compute_align(x, var, length = NULL, align = 0.5, dir = "x")

Arguments
- **x**: Dataset-like object to align. Built-in methods for data frames, grouped data
  frames and ggvis visualisations.
- **var**: Name of variable to compute width of.
- **length**: An absolute length to use. If NULL (the default), the width will be equivalent to
  the resolution of the data.
- **align**: Where does the existing variable fall on the new bins? 0 = left edge, 0.5 = center,
  1 = right edge.
- **dir**: Direction, i.e. "x" or "y". Used to generate variable names in output.
compute_align

Details

An absolute width for each x can be specified by using the width argument. If width is NULL (the default), it will use the resolution of the data as the width.

Value

The original data frame, with additional columns:

- 'dir'min_: left boundary of bin
- 'dir'max_: right boundary of bin
- 'dir'len_: width of bin

See Also

compute_bin For counting cases within ranges of a continuous variable.
compute_count For counting cases at specific values of a variable.

Examples

```r
mtcars %>% compute_count(~disp) %>% compute_align(~x_)
mtcars %>% compute_count(~mpg) %>% compute_align(~x_)

# Use a specific width
pressure %>% compute_count(~temperature) %>% compute_align(~x_)
pressure %>% compute_count(~temperature) %>% compute_align(~x_, length = 5)

# It doesn't matter whether you transform inside or outside of a vis
mtcars %>% compute_count(~cyl, ~wt) %>%
  compute_align(~x_, length = .5) %>%
ggvis(x = ~xmin_, x2 = ~xmax_, y = ~count_, y2 = 0) %>%
layer_rects()

mtcars %>%
ggvis(x = ~xmin_, x2 = ~xmax_, y = ~count_, y2 = 0) %>%
compute_count(~cyl, ~wt) %>%
compute_align(~x_) %>%
layer_rects()

# Varying align
mtcars %>%
ggvis(x = ~xmin_, x2 = ~xmax_, y = ~count_, y2 = 0) %>%
compute_count(~cyl, ~wt) %>%
compute_align(~x_, length = 0.5, align = input_slider(0, 1)) %>%
layer_rects()
```
compute_bin

Bin data along a continuous variable

Description

Bin data along a continuous variable

Usage

compute_bin(x, x_var = NULL, w_var = NULL, width = NULL, center = NULL,
            boundary = NULL, closed = c("right", "left"), pad = FALSE, binwidth)

Arguments

x                      Dataset-like object to bin. Built-in methods for data frames, grouped data frames
x_var, w_var           Names of x and weight variables. The x variable must be continuous.
width                   The width of the bins. The default is NULL, which yields 30 bins that cover the
                        range of the data. You should always override this value, exploring multiple
                        widths to find the best to illustrate the stories in your data.
center                  The center of one of the bins. Note that if center is above or below the range of
                        the data, things will be shifted by an appropriate number of widths. To center
                        on integers, for example, use width=1 and center=0, even if 0 is outside the
                        range of the data. At most one of center and boundary may be specified.
boundary                A boundary between two bins. As with center, things are shifted when boundary
                        is outside the range of the data. For example, to center on integers, use width = 1
                        and boundary = 0.5, even if 1 is outside the range of the data. At most one of
                        center and boundary may be specified.
closed                  One of "right" or "left" indicating whether right or left edges of bins are
                        included in the bin.
pad                     If TRUE, adds empty bins at either end of x. This ensures frequency polygons
                        touch 0. Defaults to FALSE.
binwidth                Deprecated; use width instead.

Value

A data frame with columns:

- **count_** the number of points
- **x_** mid-point of bin
- **xmin_** left boundary of bin
- **xmax_** right boundary of bin
- **width_** width of bin
compute_boxplot

**Calculate boxplot values**

description

Calculate boxplot values

Usage

compute_boxplot(x, var = NULL, coef = 1.5)

Arguments

- `x`  
  Dataset-like object to compute boxplot values. There are built-in methods for data frames, grouped data frames, and `ggvis` visualisations.

- `var`  
  Name of variable for which to compute boxplot values. The variable must be continuous.

- `coef`  
  The maximum length of the whiskers as multiple of the inter-quartile range. Default value is 1.5.

Value

A data frame with columns:

- `min_`  
  Lower whisker = smallest observation greater than or equal to lower hinge - 1.5 * IQR

See Also

- `compute_count`  
  For counting cases at specific locations of a continuous variable. This is useful when the variable is continuous but the data is granular.

Examples

```R
mtcars %>% compute_bin(~mpg)
mtcars %>% compute_bin(~mpg, width = 10)
mtcars %>% group_by(cyl) %>% compute_bin(~mpg, width = 10)

# It doesn't matter whether you transform inside or outside of a vis
mtcars %>% compute_bin(~mpg) %>% ggvis(~x, ~count) %>% layer_paths()
mtcars %>% ggvis(~ x, ~ count) %>% compute_bin(~mpg) %>% layer_paths()

# Missing values get own bin
mtcars2 <- mtcars
mtcars2$mpg[sample(32, 5)] <- NA
mtcars2 %>% compute_bin(~mpg, width = 10)

# But are currently silently dropped in histograms
mtcars2 %>% ggvis() %>% layer_histograms(~mpg)
```
lower_ Lower hinge (25th percentile)
median_ Median (50th percentile)
upper_ Upper hinge (75th percentile)
max_ Upper whisker = largest observation less than or equal to upper hinge + 1.5 * IQR
outliers_ A vector of values that are outside of the min and max

See Also
layer_boxplots

Examples
mtcars %>% compute_boxplot(~mpg)
mtcars %>% group_by(cyl) %>% compute_boxplot(~mpg)

Value
A data frame with columns:
count_ the number of points
x_ the x value where the count was made

The width of each "bin" is set to the resolution of the data – that is, the smallest difference between two x values.

See Also
compute_bin For counting cases within ranges of a continuous variable.
compute_align For calculating the "width" of data.
compute_density

Examples

```r
mtcars %>% compute_count(~cyl)
```
# Weight the counts by car weight value
```r
mtcars %>% compute_count(~cyl, ~wt)
```
# If there's one weight value at each x, it effectively just renames columns.
```r
pressure %>% compute_count(~temperature, ~pressure)
```
# Also get the width of each bin
```r
pressure %>% compute_count(~temperature, ~pressure) %>% compute_align(~x_)
```
# It doesn't matter whether you transform inside or outside of a vis
```r
mtcars %>% compute_count(~cyl, ~wt) %>%
  compute_align(~x_) %>%
  ggvis(x = ~xmin_, x2 = ~xmax_, y = ~count_, y2 = 0) %>%
  layer_rects()
```
```r
mtcars %>%
  ggvis(x = ~xmin_, x2 = ~xmax_, y = ~count_, y2 = 0) %>%
  compute_count(~cyl, ~wt) %>%
  compute_align(~x_) %>%
  layer_rects()
```

compute_density  Compute density of data.

Description

Compute density of data.

Usage

```r
compute_density(x, x_var, w_var = NULL, kernel = "gaussian", trim = FALSE, n = 256L, na.rm = FALSE, ...)
```

Arguments

- `x`  
  Dataset (data frame, grouped_df or ggvis) object to work with.
- `x_var, w_var`  
  Names of variables to use for x position, and for weights.
- `kernel`  
  Smoothing kernel. See `density` for details.
- `trim`  
  If TRUE, the default, density estimates are trimmed to the actual range of the data. If FALSE, they are extended by the default 3 bandwidths (as specified by the cut parameter to `density`).
- `n`  
  Number of points (along x) to use in the density estimate.
- `na.rm`  
  If TRUE missing values will be silently removed, otherwise they will be removed with a warning.
- `...`  
  Additional arguments passed on to `density`. 
compute_model_prediction

**Value**

A data frame with columns:

- pred_ regularly spaced grid of n locations
- resp_ density estimate

**Examples**

```r
mtcars %>% compute_density(~mpg, n = 5)
mtcars %>% group_by(cyl) %>% compute_density(~mpg, n = 5)
mtcars %>% ggvis(~mpg) %>% compute_density(~mpg, n = 5) %>%
  layer_points(~pred_, ~resp_)
```

**Description**

Create a model of a data set and compute predictions.

**Usage**

```r
compute_model_prediction(x, formula, ..., model = NULL, se = FALSE,
                         level = 0.95, n = 80L, domain = NULL, method)
compute_smooth(x, formula, ..., span = 0.75, se = FALSE)
```

**Arguments**

- `x` Dataset-like object to model and predict. Built-in methods for data frames,
grouped data frames and ggvis visualisations.
- `formula` Formula passed to modelling function. Can use any variables from data.
- `...` arguments passed on to model function
- `model` Model fitting function to use - it must support R’s standard modelling inter-
facing, taking a formula and data frame as input, and returning predictions with
`predict`. If not supplied, will use `loess` for <= 1000 points, otherwise it will
use `gam`. Other modelling functions that will work include `lm`, `glm` and `rlm`.
- `se` include standard errors in output? Requires appropriate method of `predict_grid`,
since the interface for returning predictions with standard errors is not consistent
acrossing modelling frameworks.
- `level` the confidence level of the standard errors.
- `n` the number of grid points to use in the prediction
compute_model_prediction

domain
If NULL (the default), the domain of the predicted values will be the same as
the domain of the prediction variable in the data. It can also be a two-element
numeric vector specifying the min and max.

method
Deprecated. Please use model instead.

span
Smoothing span used for loess model.

Details

compute_model_prediction fits a model to the data and makes predictions with it. compute_smooth
is a special case of model predictions where the model is a smooth loess curve whose smoothness
is controlled by the span parameter.

Value

A data frame with columns:

<table>
<thead>
<tr>
<th>resp_</th>
<th>regularly spaced grid of n locations</th>
</tr>
</thead>
<tbody>
<tr>
<td>pred_</td>
<td>predicted value from model</td>
</tr>
<tr>
<td>pred_lwr_ and pred_upr_</td>
<td>upper and lower bounds of confidence interval (if se = TRUE)</td>
</tr>
<tr>
<td>pred_se_</td>
<td>the standard error (width of the confidence interval) (if se = TRUE)</td>
</tr>
</tbody>
</table>

Examples

# Use a small value of n for these examples
mtcars %>% compute_model_prediction(mpg ~ wt, n = 10)
mtcars %>% compute_model_prediction(mpg ~ wt, n = 10, se = TRUE)
mtcars %>% group_by(cyl) %>% compute_model_prediction(mpg ~ wt, n = 10)

# compute_smooth defaults to loess
mtcars %>% compute_smooth(mpg ~ wt)

# Override model to suppress message or change approach
mtcars %>% compute_model_prediction(mpg ~ wt, n = 10, model = "loess")
mtcars %>% compute_model_prediction(mpg ~ wt, n = 10, model = "lm")

# Set the domain manually
mtcars %>%
  compute_model_prediction(mpg ~ wt, n = 20, model = "lm", domain = c(0, 8))

# Plot the results
mtcars %>% compute_model_prediction(mpg ~ wt) %>%
ggvis(~pred_, ~resp_) %>%
layer_paths()
mtcars %>% ggvvis() %>%
compute_model_prediction(mpg ~ wt) %>%
layer_paths(~pred_, ~resp_)
compute_stack  

Stack overlapping data.

Description

Stack overlapping data.

Usage

compute_stack(x, stack_var = NULL, group_var = NULL)

Arguments

x            A data object
stack_var    A string specifying the stacking variable.
group_var    A string specifying the grouping variable.

Value

A data frame with columns:

stack_upr_  the lower y coordinate for a stack bar
stack_lwr_  the upper y coordinate for a stack bar

Examples

mtcars %>% cbind(count = 1) %>% compute_stack(~count, ~cyl)

# Shouldn't use or affect existing grouping
mtcars %>% cbind(count = 1) %>% group_by(am) %>% compute_stack(~count, ~cyl)

# If given a ggvis object, will use x variable for stacking by default
mtcars %>% ggvis(x = ~cyl, y = ~wt) %>%
  compute_stack(stack_var = ~wt, group_var = ~cyl) %>%
  layer_rects(x = ~cyl - 0.5, x2 = ~cyl + 0.5, y = ~stack_upr_,
              y2 = ~stack_lwr_)

# Collapse across hair & eye colour data across sex
hec <- as.data.frame(xtabs(Freq ~ Hair + Eye, HairEyeColor))
hec %>% compute_stack(~Freq, ~Hair)

# Without stacking - bars overlap
hec %>% ggvis(~Hair, ~Freq, fill = ~Eye, fillOpacity := 0.5) %>%
  layer_rects(y2 = 0, width = band())

# With stacking
hec %>% ggvis(x = ~Hair, y = ~Freq, fill = ~Eye, fillOpacity := 0.5) %>%
  compute_stack(~Freq, ~Hair) %>%
  layer_rects(y = ~stack_lwr_, y2 = ~stack_upr_, width = band())
# layer_bars stacks automatically:
hec ggvis(HHair, HFreq, fill = HEye, fillOpacity := 0.5) group_by(EEye) layer_bars(width = 1)

count data at each location of a categorical variable

describe

count data at each location of a categorical variable

use

count_tabulate(x, x_var, w_var = NULL)

arguments

x
  dataset-like object to count. built-in methods for data frames, grouped data frames and ggvis visualisations.

x_var, w_var
  names of x and weight variables.

value

data frame with columns:

count
  number of points

x
  value of bin

see also

count_bin
  for counting cases within ranges of a continuous variable.

count_count
  for counting cases at specific locations of a continuous variable. this is useful when the variable is continuous but the data is granular.

examples

library(dplyr)
# the tabulated column must be countable (not numeric)
## not run: mtcars %>% count_tabulate(~cyl)
mtcars %>% mutate(cyl = factor(cyl)) %>% count_tabulate(~cyl)

# or equivalently:
mtcars %>% count_tabulate(~factor(cyl))

# if there's one weight value at each x, it effectively just renames columns.
pressure %>% count_tabulate(~factor(temperature), ~pressure)
# It doesn't matter whether you transform inside or outside of a vis
mtcars %>% compute_tabulate(~factor(cyl)) %>%
ggvis(x = ~x, y = ~count, y2 = 0) %>%
layer_rects(width = band())

mtcars %>%
ggvis(x = ~x, y = ~count, y2 = 0) %>%
compute_tabulate(~factor(cyl)) %>%
layer_rects(width = band())

# compute_tabulate is used automatically in layer_bars when no y prop
# is supplied.
mtcars %>% ggvis(x = ~factor(cyl)) %>% layer_bars()

---------

explain

**Explain details of an object**

**Description**

This is a generic function which gives more details about an object than print, and is more focussed on human readable output than str.

**See Also**

dplyr::explain for more information.

**Examples**

```r
p <- mtcars %>% ggvis(x = ~cyl) %>% layer_bars()
explain(p)
```

---------

explain.ggvis

*Print out the structure of a ggvis object in a friendly format*

**Description**

Print out the structure of a ggvis object in a friendly format

**Usage**

```r
## S3 method for class 'ggvis'
explain(x, ...)
```

**Arguments**

- `x` Visualisation to explain
- `...` Needed for compatibility with generic. Ignored by this method.
export_png

Export a PNG or SVG from a ggvis object

Description
This requires that the external program vg2png is installed. This is part of the vega node.js module.

Usage
export_png(vis, file = NULL)
export_svg(vis, file = NULL)

Arguments
vis A ggvis object.
file Output file name. If NULL, defaults to "plot.svg" or "plot.png".

See Also
https://github.com/trifacta/vega for information on installing vg2png and vg2svg.

Examples
## Not run:
mtcars %>% ggvis(x = ~wt) %>% export_png()
## End(Not run)

get_data
Get data from a ggvis object

Description
This function is useful for inspecting the data in a ggvis object.

Usage
get_data(vis)

Arguments
vis A ggvis object.

Examples
p <- cocaine %>% ggvis(~price) %>% layer_bars()
get_data(p)
**ggvis**

*Visualise a data set with a ggvis graphic.*

**Description**

ggvis is used to turn a dataset into a visualisation, setting up default mappings between variables in the dataset and visual properties. Nothing will be displayed until you add additional layers.

**Usage**

ggvis(data = NULL, ..., env = parent.frame())

**Arguments**

data A data object.

... Property mappings. If not named, the first two mappings are taken to be x and y. Common properties are x, y, stroke, fill, opacity, shape

env Environment in which to evaluate properties.

**Examples**

```r
# If you don't supply a layer, ggvis uses layer_guess() to guess at
# an appropriate type:
mtcars %>% ggvis(~mpg, ~wt)
mtcars %>% ggvis(~mpg, ~wt, fill = ~cyl)
mtcars %>% ggvis(~mpg, ~wt, fill := "red")
mtcars %>% ggvis(~mpg)

# ggvis has a functional interface: every ggvis function takes a ggvis
# an input and returns a modified ggvis as output.
layer_points(ggvis(mtcars, ~mpg, ~wt))

# To make working with this interface more natural, ggvis imports the
# pipe operator from magrittr. x %>% f(y) is equivalent to f(x, y) so
# we can rewrite the previous command as
mtcars %>% ggvis(~mpg, ~wt) %>% layer_points()

# For more complicated plots, add a line break after %>%
mtcars %>%
ggvis(~mpg, ~wt) %>%
layer_points() %>%
layer_smooths()
```
**ggvisControlOutput**

*Create a ggvis control output element in UI*

**Description**

This is effectively the same as `uiOutput`, except that on the client side it may call some plot resizing functions after new controls are drawn.

**Usage**

```r
ggvisControlOutput(outputId, plotId = NULL)
```

**Arguments**

- `outputId` The output variable to read the value from.
- `plotId` An optional plot ID or vector of plot IDs. The plots will have their `.onControlOutput` functions called after the controls are drawn.

**Details**

`ggvisControlOutput` is intended to be used with `bind_shiny` on the server side.

**Examples**

```r
ggvisControlOutput("plot1")
```

---

**ggvis_message**

*Send a message to ggvis running on client*

**Description**

This will be sent to the client and passed to a handler in ggvis.messages on the client side. The handler is specified by `type`.

**Usage**

```r
ggvis_message(session, type, data = NULL, id = NULL)
```

**Arguments**

- `session` A session object.
- `type` A string representing the type of the message.
- `data` An object (typically a list) containing information for the client.
- `id` A unique identifier for ggvis message handler (optional).
**group_by**

*Divide data into groups.*

**Description**

Divide data into groups.

**Arguments**

- `x` a visualisation
- `...` variables to group by.
- `add` By default, when `add = FALSE`, `group_by` will override existing groups. To instead add to the existing groups, use `add = TRUE`

---

**handle_brush**

*Handle brush events on a visualisation.*

**Description**

Currently for brush events to be triggered on a visualisation, you must use a `.brush` property. This limitation will be lifted in the future.

**Usage**

```r
handle_brush(vis, on_move = NULL, fill = "black")
```

**Arguments**

- `vis` Visualisation to listen to.
- `on_move` Callback function with arguments:
  - `items` A data frame containing information about the items under the plot. An empty data.frame if no points under the brush.
  - `page_loc` Location of the brush with respect to the page
  - `plot_loc` Location of the brush with respect to the plot
  - `session` The session, used to communicate with the browser
- `fill` Colour of the brush.

**Examples**

```r
# Display tooltip when objects are brushed
mtcars %>%
ggvis(x = ~wt, y = ~mpg, size.brush := 400) %>%
layer_points() %>%
handle_brush(function(items, page_loc, session, ...) {
  show_tooltip(session, page_loc$r + 5, page_loc$t, html = nrow(items))
})
```
**handle_click**  
*Handle mouse actions on marks.*

**Description**

Handle mouse actions on marks.

**Usage**

```r
handle_click(vis, on_click = NULL)

handle_hover(vis, on_mouse_over = NULL, on_mouse_out = NULL)
```

**Arguments**

<table>
<thead>
<tr>
<th>vis</th>
<th>Visualisation to listen to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>on_click, on_mouse_over</td>
<td>Callback function with arguments:</td>
</tr>
<tr>
<td>data</td>
<td>A data frame with one row</td>
</tr>
<tr>
<td>location</td>
<td>A named list with components x and y</td>
</tr>
<tr>
<td>session</td>
<td>The session, used to communicate with the browser</td>
</tr>
<tr>
<td>on_mouse_out</td>
<td>Callback function with argument:</td>
</tr>
<tr>
<td>session</td>
<td>The session, used to communicate with the browser</td>
</tr>
</tbody>
</table>

**Examples**

```r
location <- function(location, ...) cat(location$x, "x", location$y, 
mtcars %>% ggvis(~mpg, ~wt) %>% layer_points() %>%
  handle_click(location)
mtcars %>% ggvis(~mpg, ~wt) %>% layer_points() %>%
  handle_hover(function(...) cat("over\n"), function(...) cat("off\n"))
mtcars %>% ggvis(~mpg, ~wt) %>% layer_points() %>%
  handle_hover(function(data, ...) str(data))
```

---

**handle_resize**  
*Handlers and interactive inputs for plot sizing.*

**Description**

Handlers and interactive inputs for plot sizing.
Usage

handle_resize(vis, on_resize)
plot_width(vis)
plot_height(vis)

Arguments

vis Visualisation to listen to.
on_resize Callback function with arguments:
  width, height Width and height in pixels
  padding A named list of four components giving the padding in each direction
  session The session, used to communicate with the browser

Examples

# This example just prints out the current dimensions to the console
mtcars %>% ggvis(~mpg, ~wt) %>%
  layer_points() %>%
  handle_resize(function(width, height, ...) cat(width, "\n", height, "\n"))

# Use plot_width() and plot_height() to dynamically get the plot size
# inside the plot.
mtcars %>% ggvis(~mpg, ~wt) %>%
  layer_text(text := plot_width())
mtcars %>% ggvis(~mpg, ~wt) %>%
  layer_text(text := plot_height())

input_checkbox Create an interactive checkbox.

Description

Create an interactive checkbox.

Usage

input_checkbox(value = FALSE, label = "", id = rand_id("checkbox_"),
  map = identity)

Arguments

value Initial value (TRUE or FALSE).
label Display label for the control, or NULL for no label.
id A unique identifier for this input. Usually generated automatically.
map A function with single argument x, the value of the control on the client. Returns a modified value.
input_select

See Also
Other interactive input: input_checkboxgroup, input_radiobuttons, input_select, input_numeric, input_text, input_slider

Examples

input_checkbox(label = "Confidence interval")
input_checkbox(label = "Confidence interval", value = TRUE)

# Used in layer_smooths
mtcars %>% ggvis(~wt, ~mpg) %>%
  layer_smooths(se = input_checkbox(label = "Confidence interval"))

# Used with a map function, to convert the boolean to another type of value
model_type <- input_checkbox(label = "Use flexible curve",
                           map = function(val) if(val) "loess" else "lm")
mtcars %>% ggvis(~wt, ~mpg) %>%
  layer_model_predictions(model = model_type)

---

input_select

Create interactive control to select one (or more options) from a list.

Description

- input_radiobuttons only ever selects one value
- input_checkboxgroup can always select multiple values
- input_select can select only one if multiple = FALSE, otherwise the user can select multiple by using modifier keys

Usage

input_select(choices, selected = NULL, multiple = FALSE, label = "",
             id = rand_id("select."), map = identity, selectize = FALSE)

input_radiobuttons(choices, selected = NULL, label = "",
                    id = rand_id("radio."), map = identity)

input_checkboxgroup(choices, selected = NULL, label = "",
                     id = rand_id("radio."), map = identity)

Arguments

choices List of values to select from. If elements of the list are named then that name rather than the value is displayed to the user.

selected The initially selected value (or multiple values if multiple = TRUE). If not specified then defaults to the first value for single-select lists and no values for multiple select lists.
multiple Is selection of multiple items allowed?
label Display label for the control, or NULL for no label.
id A unique identifier for this input. Usually generated automatically.
map A function with single argument x, the value of the control on the client. Returns a modified value.
selectize Whether to use selectize.js or not.

See Also
Other interactive input: input_checkbox; input_numeric; input_text; input_slider

Examples

# Dropdown
input_select(c("a", "b", "c"))
input_select(c("a", "b", "c"), multiple = TRUE)
input_select(c("a", "b", "c"), selected = "c")

# If you want to select variable names, you need to convert
# the output of the input to a name with map so that they get
# computed correctly
input_select(names(mtcars), map = as.name)

# Radio buttons
input_radiobuttons(choices = c("Linear" = "lm", "LOESS" = "loess"),
                   label = "Model type")
input_radiobuttons(choices = c("Linear" = "lm", "LOESS" = "loess"),
                   selected = "loess",
                   label = "Model type")

# Used in layer_model_predictions
mtcars %>% ggvis(~wt, ~mpg) %>%
layer_model_predictions(model = input_radiobuttons(
    choices = c("Linear" = "lm", "LOESS" = "loess"),
    selected = "loess",
    label = "Model type"))

# Checkbox group
mtcars %>% ggvis(x = ~wt, y = ~mpg) %>%
layer_points(
  fill := input_checkboxgroup(
    choices = c("Red" = "r", "Green" = "g", "Blue" = "b"),
    label = "Point color components",
    map = function(val) {
      rgb(0.8 * "r" %in% val, 0.8 * "g" %in% val, 0.8 * "b" %in% val)
    }
  )
)
Create an interactive slider.

**Arguments**

- **min**  
The minimum value (inclusive) that can be selected.
- **max**  
The maximum value (inclusive) that can be selected.
- **value**  
The initial value of the slider. A numeric vector of length one will create a regular slider; a numeric vector of length two will create a double-ended range slider. A warning will be issued if the value doesn’t fit between min and max.
- **step**  
Specifies the interval between each selectable value on the slider (if NULL, a heuristic is used to determine the step size).
- **round**  
TRUE to round all values to the nearest integer; FALSE if no rounding is desired; or an integer to round to that number of digits (for example, 1 will round to the nearest 10, and -2 will round to the nearest .01). Any rounding will be applied after snapping to the nearest step.
- **format**  
Deprecated.
- **locale**  
Deprecated.
- **ticks**  
FALSE to hide tick marks, TRUE to show them according to some simple heuristics.
- **animate**  
TRUE to show simple animation controls with default settings; FALSE not to; or a custom settings list, such as those created using animationOptions.
- **sep**  
Separator between thousands places in numbers.
- **pre**  
A prefix string to put in front of the value.
- **post**  
A suffix string to put after the value.
- **label**  
Display label for the control, or NULL for no label.
- **id**  
A unique identifier for this input. Usually generated automatically.
- **map**  
A function with single argument x, the value of the control on the client. Returns a modified value.
See Also

Other interactive input: `input_checkboxgroup`, `input_radiobuttons`, `input_select`; `input_checkbox`; `input_numeric`, `input_text`

Examples

```r
input_slider(0, 100)
input_slider(0, 100, label = "binwidth")
input_slider(0, 100, value = 50)

# Supply two values to value to make a double-ended sliders
input_slider(0, 100, c(25, 75))

# You can use map to transform the outputs
input_slider(-5, 5, label = "Log scale", map = function(x) 10 ^ x)
```

---

**input_text**

Create an interactive text or numeric input box.

Description

`input_numeric` only allows numbers and comes with a spin box control. `input_text` allows any type of input.

Usage

```r
input_text(value, label = "", id = rand_id("text"), map = identity)

input_numeric(value, label = "", id = rand_id("numeric"), map = identity)
```

Arguments

- **value**: Initial value.
- **label**: Display label for the control, or NULL for no label.
- **id**: A unique identifier for this input. Usually generated automatically.
- **map**: A function with single argument `x`, the value of the control on the client. Returns a modified value.

See Also

Other interactive input: `input_checkboxgroup`, `input_radiobuttons`, `input_select`; `input_checkbox`; `input_slider`
is.broker

Examples

```r
fill_text <- input_text(label = "Point color", value = "red")
mtcars %>% ggvis(~wt, ~mpg, fill := fill_text) %>% layer_bars()

size_num <- input_numeric(label = "Point size", value = 25)
mtcars %>% ggvis(~wt, ~mpg, size := size_num) %>% layer_points()
```

is.broker

Determine if an object is a broker object

Description

Determine if an object is a broker object

Usage

```r
is.broker(x)
```

Arguments

- `x` An object to test.

layer_bars

Display data with bars (a barchart).

Description

This will add bars to a plot. The exact behavior is complicated because the term bar chart is used to describe four important variations on a theme. The action of `layer_bars` depends on two factors: whether or not a y prop has been specified, and whether the x props is continuous or categorical.

Usage

```r
layer_bars(vis, ..., stack = TRUE, width = NULL)
```

Arguments

- `vis` Visualisation to modify
- `...` Visual properties used to override defaults.
- `stack` If there are multiple bars to be drawn at an x location, should the bars be stacked? If FALSE, the bars will be overplotted on each other.
- `width` Width of each bar. When x is continuous, this controls the width in the same units as x. When x is categorical, this controls the width as a proportion of the spacing between items (default is 0.9).
Visualisations

If no y prop has been specified, then this will count the number of entries at each unique x value. There will be one bar at each unique x value, and the y value (or height) of each bar will represent the count at that x value.

If a y prop has been specified, then those y values will be used as weights for a weighted count at each unique x value. If no x values appear more than once in the data, then the end result is a plot where the height of the bar at each x value is simply the y value. However, if an x value appear more than once in the data, then this will sum up the y values at each x.

If the x variable is continuous, then a continuous x axis will be used, and the width of each bar is by default equal to the resolution of the data – that is, the smallest difference between any two x values.

If the x variable is categorical, then a categorical x axis will be used. By default, the width of each bar is 0.9 times the space between the items.

See Also

layer_histograms For bar graphs of counts at each unique x value, in contrast to a histogram’s bins along x ranges.
compute_count and compute_tabulate for more information on how data is transformed.

Examples

# Discrete x: bar graph of counts at each x value
cocaine %>% ggvis(~state) %>% layer_bars()
# Continuous x: bar graph of counts at unique locations
cocaine %>% ggvis(~month) %>% layer_bars()

# Use y prop to weight by additional variable. This is also useful
# if you have pretabulated data
cocaine %>% ggvis(~state, ~weight) %>% layer_bars()
cocaine %>% ggvis(~month, ~weight) %>% layer_bars()

# For continuous x, layer_bars is useful when the variable has a few
# unique values that you want to preserve. If you have many unique
# values and you want to bin, use layer_histogram
cocaine %>% ggvis(~price) %>% layer_bars()
cocaine %>% ggvis(~price) %>% layer_histograms(width = 100)

# If you have unique x values, you can use layer_bars() as an alternative
# to layer_points()
pressure %>% ggvis(~temperature, ~pressure) %>% layer_points()
presure %>% ggvis(~temperature, ~pressure) %>% layer_bars()

# When x is continuous, width controls the width in x units
pressure %>% ggvis(~temperature, ~pressure) %>% layer_bars(width = 10)
# When x is categorical, width is proportional to spacing between bars
pressure %>% ggvis(~factor(temperature), ~pressure) %>%
layer_bars(width = 0.5)
layer_boxplots

Display data with a boxplot.

Description

This will add boxplots to a plot. The action of layer_boxplots depends on whether the x prop is continuous or categorical.

Usage

layer_boxplots(vis, ..., coef = 1.5, width = NULL)

Arguments

vis Visualisation to modify
...
coef The maximum length of the whiskers as multiple of the inter-quartile range. Default value is 1.5.
width Width of each bar. When x is continuous, this controls the width in the same units as x. When x is categorical, this controls the width as a proportion of the spacing between items (default is 0.9).

Details

The upper and lower "hinges" correspond to the first and third quartiles (the 25th and 75th percentiles). This differs slightly from the method used by the boxplot function, and may be apparent with small samples. See boxplot.stats for more information on how hinge positions are calculated for boxplot.

The upper whisker extends from the hinge to the highest value that is within 1.5 * IQR of the hinge, where IQR is the inter-quartile range, or distance between the first and third quartiles. The lower whisker extends from the hinge to the lowest value within 1.5 * IQR of the hinge. Data beyond the end of the whiskers are outliers and plotted as points (as specified by Tukey).

See Also

compute_boxplot for more information on how data is transformed.
Examples

library(dplyr)

mtcars %>% ggvis(~factor(cyl), ~mpg) %>% layer_boxplots()
# Set the width of the boxes to half the space between tick marks
mtcars %>% ggvis(~factor(cyl), ~mpg) %>% layer_boxplots(width = 0.5)

# Continuous x: boxes fill width between data values
mtcars %>% ggvis(~cyl, ~mpg) %>% layer_boxplots()
# Settings width=0.5 makes it 0.5 wide in the data space, which is 1/4 of the
# distance between data values in this particular case.
mtcars %>% ggvis(~cyl, ~mpg) %>% layer_boxplots(width = 0.5)

# Smaller outlier points
mtcars %>% ggvis(~factor(cyl), ~mpg) %>% layer_boxplots(size := 20)

layer_densities

Transformation: density estimate

Description

transform_density is a data transformation that computes a kernel density estimate from a dataset.
layer_density combines transform_density with mark_path and mark_area to display a smooth
line and its standard error.

Usage

layer_densities(vis, ..., kernel = "gaussian", adjust = 1,
                  density_args = list(), area = TRUE)

Arguments

vis The visualisation to modify
...
kernel Smoothing kernel. See density for details.
adjust Multiple the default bandwidth by this amount. Useful for controlling wiggli-
ness of density.
density_args Other arguments passed on to compute_density and thence to density.
area Should there be a shaded region drawn under the curve?

Examples

# Basic density estimate
faithful %>% ggvis(~waiting) %>% layer_densities()
faithful %>% ggvis(~waiting) %>% layer_densities(area = FALSE)

# Control bandwidth with adjust
layer_guess

Guess the right type of layer based on current properties.

Description

layer_guess provides the magic behind the default behaviour of ggvis.

Usage

layer_guess(vis, ...)

Arguments

vis The visualisation to add the new layer to.
...

Other arguments passed on individual layers.

Defaults

- Continuous x, layer_histograms
- Categorical x, layer_bars
- Continuous x and y, layer_points

Examples

# A scatterplot:
mtcars %>% ggvis(~mpg, ~wt)
mtcars %>% ggvis(~mpg, ~wt) %>% layer_guess()

# A histogram:
mtcars %>% ggvis(~mpg)
mtcars %>% ggvis(~mpg) %>% layer_guess()
**layer_histograms**

*Display binned data*

**Description**

Display binned data

**Usage**

```r
layer_histograms(vis, ..., width = NULL, center = NULL, boundary = NULL,
                  closed = c("right", "left"), stack = TRUE, binwidth)
```

```r
layer_freqpolys(vis, ..., width = NULL, center = NULL, boundary = NULL,
                 closed = c("right", "left"), binwidth)
```

**Arguments**

- `vis` Visualisation to modify
- `...` Visual properties used to override defaults.
- `width` The width of the bins. The default is `NULL`, which yields 30 bins that cover the range of the data. You should always override this value, exploring multiple widths to find the best to illustrate the stories in your data.
- `center` The center of one of the bins. Note that if center is above or below the range of the data, things will be shifted by an appropriate number of widths. To center on integers, for example, use `width=1` and `center=0`, even if 0 is outside the range of the data. At most one of `center` and `boundary` may be specified.
- `boundary` A boundary between two bins. As with `center`, things are shifted when `boundary` is outside the range of the data. For example, to center on integers, use `width = 1` and `boundary = 0.5`, even if 1 is outside the range of the data. At most one of `center` and `boundary` may be specified.
- `closed` One of "right" or "left" indicating whether right or left edges of bins are included in the bin.
- `stack` If `TRUE`, will automatically stack overlapping bars.
- `binwidth` Deprecated; use `width` instead.

**See Also**

- `layer_bars` For bar graphs of counts at each unique x value, in contrast to a histogram’s bins along x ranges.
Examples

```r
# Create histograms and frequency polygons with layers
mtcars %>% ggvis(~mpg) %>% layer_histograms()
mtcars %>% ggvis(~mpg) %>% layer_histograms(width = 2)
mtcars %>% ggvis(~mpg) %>% layer_freqpolys(width = 2)

# These are equivalent to combining compute_bin with the corresponding
# mark
mtcars %>% compute_bin(~mpg) %>% ggvis(~x, ~count) %>% layer_paths()

# With grouping
mtcars %>% ggvis(~mpg, fill = ~factor(cyl)) %>% group_by(cyl) %>%
  layer_histograms(width = 2)
mtcars %>% ggvis(~mpg, stroke = ~factor(cyl)) %>% group_by(cyl) %>%
  layer_freqpolys(width = 2)
```

---

**layer_lines**

*Layer lines on a plot.*

Description

`layer_lines` differs from `layer_paths` in that `layer_lines` sorts the data on the x variable, so the line will always proceed from left to right, whereas `layer_paths` will draw a line in whatever order appears in the data.

Usage

```r
layer_lines(vis, ...)
```

Arguments

- `vis` Visualisation to modify.
- `...` Visual properties.

See Also

`layer_paths`

Examples

```r
mtcars %>% ggvis(~wt, ~mpg, stroke = ~factor(cyl)) %>% layer_lines()

# Equivalent to
mtcars %>% ggvis(~wt, ~mpg, stroke = ~factor(cyl)) %>%
  group_by(cyl) %>% dplyr::arrange(wt) %>% layer_paths()
```
layer_model_predictions

*Overlay model predictions or a smooth curve.*

**Description**

layer_model_predictions fits a model to the data and draw it with layer_paths and, optionally, layer_ribbons. layer_smooths is a special case of layering model predictions where the model is a smooth loess curve whose smoothness is controlled by the span parameter.

**Usage**

```
layer_model_predictions(vis, ..., model, formula = NULL, model_args = NULL, se = FALSE, domain = NULL)
layer_smooths(vis, ..., span = 0.75, se = FALSE)
```

**Arguments**

- **vis** Visualisation to modify
- **...** Visual properties. Stroke properties control only affect line, fill properties only affect standard error band.
- **model** Name of the model as a string, e.g. "loess", "lm", or "MASS::rlm". Must be the name of a function that produces a standard model object with a predict method. For layer_smooth this is always "loess".
- **formula** Model formula. If not supplied, guessed from the visual properties, constructing y ~ x.
- **model_args** A list of additional arguments passed on to the model function.
- **se** Also display a point-wise standard error band? Defaults to FALSE because interpretation is non-trivial.
- **domain** If NULL (the default), the domain of the predicted values will be the same as the domain of the prediction variable in the data. It can also be a two-element numeric vector specifying the min and max.
- **span** For layer_smooth, the span of the loess smoother.

**Examples**

```r
mtcars %>% ggvis(~wt, ~mpg) %>% layer_smooths()
mtcars %>% ggvis(~wt, ~mpg) %>% layer_smooths(se = TRUE)

# Use group by to display multiple smoothes
mtcars %>% ggvis(~wt, ~mpg) %>% group_by(cyl) %>% layer_smooths()

# Control appearance with props
mtcars %>% ggvis(~wt, ~mpg) %>%
  layer_smooths(se = TRUE, stroke := "red", fill := "red", strokeWidth := 5)
```
```
# Control the wiggliness with span. Default is 0.75
mtcars %>% ggvis(~wt, -mpg) %>% layer_points() %>%
  layer_smooths(span = 0.2)
mtcars %>% ggvis(~wt, -mpg) %>% layer_points() %>%
  layer_smooths(span = 1)

# Map to an input to modify interactively
mtcars %>% ggvis(~wt, -mpg) %>% layer_points() %>%
  layer_smooths(span = input_slider(0.2, 1))

# Use other modelling functions with layer_model_predictions
mtcars %>% ggvis(~wt, -mpg) %>%
  layer_points() %>%
  layer_model_predictions(model = "lm") %>%
  layer_model_predictions(model = "MASS::rlm", stroke := "red")

# Custom domain for predictions
mtcars %>% ggvis(~wt, -mpg) %>% layer_points() %>%
  layer_model_predictions(model = "lm", domain = c(0, 8))
mtcars %>% ggvis(~wt, -mpg) %>% layer_points() %>%
  layer_model_predictions(model = "lm",
                          domain = input_slider(0, 10, value = c(1, 4)))

# layer_smooths() is just compute_smooth() + layer_paths()
# Run loess or other model outside of a visualisation to see what variables
# you get.
mtcars %>% compute_smooth(mpg ~ wt)
mtcars %>% compute_model_prediction(mpg ~ wt, model = "lm")

mtcars %>%
  ggvis(~wt, -mpg) %>%
  layer_points() %>%
  compute_smooth(mpg ~ wt) %>%
  layer_paths(~pred_, ~resp_, strokeWidth := 2)
```

---

**left_right**

Interactive inputs bound to arrow keys.

**Description**

Interactive inputs bound to arrow keys.

**Usage**

```
left_right(min, max, value = (min + max)/2, step = (max - min)/40)

up_down(min, max, value = (min + max)/2, step = (max - min)/40)
```
Arguments

min  A minimum value.
max  A maximum value.
value The initial value before any keys are pressed. Defaults to half-way between min and max.
step  How much each key press changes value. Defaults to 40 steps along range

Examples

```r
size <- left_right(1, 0.01, value = 51, step = 50)
opacity <- up_down(0, 1, value = 0.9, step = 0.05)

mtcars %>% ggvis(~mpg, ~wt, size := size, opacity := opacity) %>%
layer_points()
```

---

**legend Props**

Create an axis_props object for controlling legend properties.

Description

The items in each of the lists can be a literal value, like 5 or "blue", or they can be a `scaled_value` object.

Usage

```r
legend_props(title = NULL, labels = NULL, symbols = NULL,
gradient = NULL, legend = NULL)
```

Arguments

- **title**  A named list of text properties for the legend title.
- **labels** A named list of text properties for legend labels.
- **symbols** A named list of line properties for symbols (for discrete legend items).
- **gradient** A named list of line properties a continuous color gradient.
- **legend** A named list of line properties for the overall legend. The x and y position can be set here, which will override automatic positioning.
linked_brush

Create a linked brush object.

Description

A linked brush has two sides: input and output

Usage

linked_brush(keys, fill = "red")

Arguments

keys    vector of all possible keys, if known.
fill    brush colour

Value

A list with components:

input    A function that takes a visualisation as an argument and adds an input brush to that plot
selected  A reactive providing a logical vector that describes which points are under the brush
fill      A reactive that gives the fill colour of points under the brush

Note

linked_brush is very new and is likely to change substantially in the future

Examples

lb <- linked_brush(keys = 1:nrow(mtcars), "red")

# Change the colour of the points
mtcars %>%
ggvis(~disp,  ~mpg) %>%
layer_points(fill := lb$fill, size.brush := 400) %>%
lb$input()

# Display one layer with all points and another layer with selected points
library(shiny)
mtcars %>%
ggvis(~disp,  ~mpg) %>%
layer_points(size.brush := 400) %>%
lb$input() %>%
layer_points(fill := "red", data = reactive(mtcars[lb$selected(), ]))
marks

Vega marks.

Description

These functions create mark objects, corresponding to vega marks. Marks are leaves in the plot tree, and control the details of the final rendering. Marks are equivalent to the basic geoms in ggplot2 (e.g. point, line, polygon), where ggvis layers correspond to combinations of geoms and statistical transforms.

Usage

emit_points(vis, props)
layer_points(vis, ..., data = NULL)
emit_images(vis, props)
layer_images(vis, ..., data = NULL)
emit_arcs(vis, props)
layer_arcs(vis, ..., data = NULL)
emit_ribbons(vis, props)
layer_ribbons(vis, ..., data = NULL)
emit_paths(vis, props)
layer_paths(vis, ..., data = NULL)
emit_rects(vis, props)
layer_rects(vis, ..., data = NULL)
emit_text(vis, props)
layer_text(vis, ..., data = NULL)

Arguments

vis Visualisation to modify
props,... A props object, named according to the properties listed below.
data An optional dataset, if you want to override the usual data inheritance for this mark.
Details

Note that by supplying a fill property to mark_path will produce a filled property. mark_point is an alias to mark_symbol.

Properties

You can set the following mark properties:

- x The first (typically left-most) x-coordinate.
- x2 The second (typically right-most) x-coordinate.
- width The width of the mark (if supported).
- y The first (typically top-most) y-coordinate.
- y2 The second (typically bottom-most) y-coordinate.
- height The height of the mark (if supported).
- opacity The overall opacity.
- fill The fill color.
- fillOpacity The fill opacity
- stroke The stroke color.
- strokeWidth The stroke width, in pixels.
- strokeOpacity The stroke opacity.
- size [symbol] The pixel area of the symbol. For example in the case of circles, the radius is determined in part by the square root of the size value.
- shape [symbol] The symbol shape to use. One of circle (default), square, cross, diamond, triangle-up, or triangle-down (symbol only)
- innerRadius [arc] The inner radius of the arc, in pixels.
- outerRadius [arc] The outer radius of the arc, in pixels.
- startAngle [arc] The start angle of the arc, in radians.
- endAngle [arc] The end angle of the arc, in radians.
- tension [area, line] Depending on the interpolation type, sets the tension parameter.
- url [image] The URL from which to retrieve the image.
- align [image, text] The horizontal alignment of the object. One of left, right, center.
- baseline [image, text] The vertical alignment of the object. One of top, middle, bottom.
- text [text] The text to display.
- dx [text] The horizontal margin, in pixels, between the text label and its anchor point. The value is ignored if the align property is center.
- dy [text] The vertical margin, in pixels, between the text label and its anchor point. The value is ignored if the baseline property is middle.
- angle [text] The rotation angle of the text, in degrees.
• font [text] The typeface to set the text in (e.g., Helvetica Neue).
• fontSize [text] The font size, in pixels.
• fontWeight [text] The font weight (e.g., bold).
• fontStyle [text] The font style (e.g., italic).

To each property, you can assign any property object (prop) either locally (i.e. in the mark), or in a parent layer.

---

property

Define property.

Description

Define property.

Usage

padding(top = NULL, right = NULL, bottom = NULL, left = NULL)

Arguments

top, right, bottom, left

Amount of padding on each border. Can either be a single number, "auto", or "strict"

Examples

p <- mtcars %>gvis(~wt, ~mpg) %>% layer_points()
p %>% set_options(padding = padding())
p %>% set_options(padding = padding(10, 10, 10, 10))

---

prop

Create a property.

Description

Properties are used to describe the visual properties of marks. You create a single property definition with prop, and manage sets of named properties with props (which also provides shortcuts for creating the most common kind of properties)
prop

Usage

prop(property, x, scale = NULL, offset = NULL, mult = NULL,
   env = parent.frame(), event = NULL, label = NULL)

is.prop(x)

is.prop_constant(x)

is.prop_variable(x)

is.prop_reactive(x)

Arguments

property A property, like "x", "x2", "y", "fill", and so on.
x The value of the property. This can be an atomic vector (a constant), a name or
   quoted call (a variable), a single-sided formula (a constant or variable depending
   on its contents), or a delayed reactive (which can be either variable or constant).
scale If NULL, automatically determine behavior by the kind of value (constant, vari-
   able, or reactive). If TRUE use the default scale associated with property. If
   FALSE, do not scale the value. Otherwise supply a string to select a custom
   scale. If x is an interactive input, then this defaults to the scale parameter of the
   input.
offset, mult Additive and multiplicative pixel offset used to adjust scaled values. These are
   useful if you want to place labels offset from points.
env If x is a quoted call this provides the environment in which to look for variables
   not in the data. You should not need this in ordinary operation.
event An event to which this property applies. One of "update", "enter", "exit", "hover",
   "brush".
label A label for this prop to use for reporting errors.

See Also

props to manage multiple properties and to succinctly create the most common types.

Examples

prop("x", 1)
prop("x", -1)
prop("fill", quote(cyl))
prop("fill", -cyl)
prop("x", input_slider(0, 100))

# If you have a variable name as a string
var <- "cyl"
prop("x", as.name(var))

# Use a custom scale

```r
c = 1

# Don't scale variable (i.e. it already makes sense in the visual space)
prop("fill", ~colour, scale = FALSE)

# Use a constant, but scaled
prop("x", 5, scale = TRUE)

# Use other events
prop("y", quote(cyl), scale = "y-2")
```

### Description

`props()` provides a tool for concise creation of prop objects using a set of conventions designed to capture the most common use cases. If you need something less common, you'll need to use `prop` to access all possible options.

### Usage

```r
props(..., .props = NULL, inherit = TRUE, env = parent.frame())
```

`is.ggvis_props(x)`

### Arguments

- `...` A set of name-value pairs. The name should be a valid vega property. The first two unnamed components are taken to be `x` and `y`. Any additional unnamed components will raise an error.
- `.props` When calling `props` from other functions, you'll often have a list of quoted function functions. You can pass that function to the `.props` argument instead of messing around with substitute. In other words, `.props` lets you opt out of the non-standard evaluation that `props` does.
- `inherit` If `TRUE`, the defaults, will inherit from properties from the parent layer If `FALSE`, it will start from nothing.
- `env` The environment in which to evaluate variable properties.
- `x` an object to test for props-ness.

### Heuristics

If the values are not already objects of class prop, props uses the following heuristics to when creating the prop:

- atomic vectors, e.g. `x = 1`: scaled = FALSE
- an interactive input, e.g. `x = input_slider`: scaled = FALSE
- a formula containing a single value, e.g. `x ~ 1`: scaled = TRUE
- a formula containing a name or expression, `x ~ mpg`: scaled = TRUE
Non-standard evaluation

`props` uses non-standard evaluation in a slightly unusual way: if you provide a formula input, the LHS of the formula will provide the name of the component. In otherwise, `props(x = y ~ 1)` is the same as `props(y ~ 1)`.

You can combine variables from the dataset and variables defined in the local environment: expressions will be evaluated in the environment which the formula was defined.

If you have the name of a variable in a string, see the `props` vignette for how to create the needed property mapping.

Enter, exit, hover, and update events

There are four different property events that the marks can use. These can, for example, be used to change the appearance of a mark when the mouse cursor is hovering over it: when the mark is hovered over, it uses the hover event, and when the mark isn’t hovered over, it uses the update event.

- **enter**: This event is used by marks when they are added to a plot.
- **update**: This event is used by marks after they have entered, and also after they have been hovered over.
- **exit**: This event is used by marks as they are removed from a plot.
- **hover**: This event is used when the mouse cursor is over the mark.

You can specify the event for a property, by putting a period and the event after the property name. For example, `props(fill.update := "black", fill.hover := "red")` will make a mark have a black fill normally, and red fill when it is hovered over.

The default event is update, so if you run `props(fill := "red")`, this is equivalent to `props(fill.update := "red")`.

In practice, the enter and exit events are useful only when the update has a duration (and is therefore not instantaneous). The update event can be thought of as the "default" state.

Key property

In addition to the standard properties, there is a special optional property called `key`. This is useful for plots with dynamic data and smooth transitions: as the data changes, the key is used to tell the plot how the new data rows should be matched to the old data rows. Note that the key must be an unscaled value. Additionally, the key property doesn’t have a event, since it is independent of enter, update, exit, and hover events.

Properties

You can set the following mark properties:

- **x**: The first (typically left-most) x-coordinate.
- **x2**: The second (typically right-most) x-coordinate.
- **width**: The width of the mark (if supported).
- **y**: The first (typically top-most) y-coordinate.
- **y2**: The second (typically bottom-most) y-coordinate.
• height The height of the mark (if supported).
• opacity The overall opacity.
• fill The fill color.
• fillOpacity The fill opacity
• stroke The stroke color.
• strokeWidth The stroke width, in pixels.
• strokeOpacity The stroke opacity.
• size [symbol] The pixel area of the symbol. For example in the case of circles, the radius is determined in part by the square root of the size value.
• shape [symbol] The symbol shape to use. One of circle (default), square, cross, diamond, triangle-up, or triangle-down (symbol only)
• innerRadius [arc] The inner radius of the arc, in pixels.
• outerRadius [arc] The outer radius of the arc, in pixels.
• startAngle [arc] The start angle of the arc, in radians.
• endAngle [arc] The end angle of the arc, in radians.
• interpolate [area, line] The line interpolation method to use. One of linear, step-before, step-after, basis, basis-open, cardinal, cardinal-open, monotone.
• tension [area, line] Depending on the interpolation type, sets the tension parameter.
• url [image] The URL from which to retrieve the image.
• align [image, text] The horizontal alignment of the object. One of left, right, center.
• baseline [image, text] The vertical alignment of the object. One of top, middle, bottom.
• text [text] The text to display.
• dx [text] The horizontal margin, in pixels, between the text label and its anchor point. The value is ignored if the align property is center.
• dy [text] The vertical margin, in pixels, between the text label and its anchor point. The value is ignored if the baseline property is middle.
• angle [text] The rotation angle of the text, in degrees.
• font [text] The typeface to set the text in (e.g., Helvetica Neue).
• fontSize [text] The font size, in pixels.
• fontWeight [text] The font weight (e.g., bold).
• fontStyle [text] The font style (e.g., italic).

To each property, you can assign any property object (prop) either locally (i.e. in the mark), or in a parent layer.
**Examples**

```r
# Set to constant values
props(x := 1, y := 2)
# Map to variables in the dataset
props(x = ~mpg, y = ~cyl)
# Set to a constant value in the data space
props(x = 1, y = 1)
# Use an interactive slider
props(opacity := input_slider(0, 1))

# To control other settings (like custom scales, mult and offset)
# use a prop object
props(prop("x", "old", scale = "x", offset = -1))

# Red when hovered over, black otherwise (these are equivalent)
props(fill := "black", fill.hover := "red")
props(fill.update := "black", fill.hover := "red")

# Use a column called id as the key (for dynamic data)
props(key := ~id)

# Explicitly create prop objects. The following are equivalent:
props(fill := ~cyl)
props(fill.update = ~cyl)
props(prop("fill", ~cyl))
props(prop("fill", ~cyl, scale = "fill", event = "update"))

# Prop objects can be programmatically created and added:
property <- "fill"
expr <- parse(text = "wt/mpg")[[1]]
p <- prop(property, expr)
props(p)

# Using .props
props(.props = list(x = 1, y = 2))
props(.props = list(x = ~mpg, y = ~cyl))
props(.props = list(quote(x := ~mpg)))
```

---

**prop_domain**

Property domain.

**Description**

Property domain.

**Usage**

`prop_domain(x, data)`
Arguments

x    property to dispatch on
data    name of data set

resolution    Compute the "resolution" of a data vector.

Description

The resolution is is the smallest non-zero distance between adjacent values. If there is only one unique value, then the resolution is defined to be one.

Usage

resolution(x, zero = TRUE)

Arguments

x    numeric vector
zero    should a zero value be automatically included in the computation of resolution

Details

If x is an integer vector, then it is assumed to represent a discrete variable, and the resolution is 1.

Examples

resolution(1:10)
resolution((1:10) - 0.5)
resolution((1:10) - 0.5, FALSE)
resolution(c(1, 10, 20, 50))
resolution(as.integer(c(1, 10, 20, 50)))  # Returns 1

scaled_value    Create a scaled_value object

Description

These are for use with legends and axes.

Usage

scaled_value(scale, value)

Arguments

scale    The name of a scale, e.g., "x", "fill".
value    A value which will be transformed using the scale.
### Description

This creates a scale object for a given scale and variable type, and adds it to a ggvis plot. The scale object is populated with default settings, which depend on the scale (e.g. fill, x, opacity) and the type of variable (e.g. numeric, nominal, ordinal). Any settings that are passed in as arguments will override the defaults.

### Arguments

- **vis**: A ggvis object.
- **scale**: The name of a scale, such as "x", "y", "fill", "stroke", etc.
- **type**: A variable type. One of "numeric", "nominal", "ordinal", "logical", "datetime".
- **...**: Other arguments passed to the scale function. See the help for `scale_numeric`, `scale_ordinal` and `scale_datetime` for more details. For example, you might supply `trans = "log"` to create a log scale.
- **name**: If NULL, the default, the scale name is the same as `scale`. Set this to a custom name to create multiple scales for stroke or fill, or (god forbid) a secondary y scale.

### Scale selection

ggvis supports the following types of scales. Typical uses for each scale type are listed below:

- **numeric**: For continuous numeric values.
- **nominal**: For character vectors and factors.
- **ordinal**: For ordered factors (these presently behave the same as nominal).
- **logical**: For logical (TRUE/FALSE) values.
- **datetime**: For dates and date-times.

Each type has a corresponding function: `scale_numeric`, `scale_nominal`, and so on.

The scale types for ggvis are mapped to scale types for Vega, which include "ordinal", "quantitative", and "time". See `ggvis_scale` for more details.

Given a scale and type, the range is selected based on the combination of the scale and type. For example, you get a different range of colours depending on whether the data is numeric, ordinal, or nominal. Some scales also set other properties. For example, nominal/ordinal position scales also add some padding so that points are spaced away from plot edges.

Not all combinations have an existing default scale. If you use a combination that does not have an existing combination, it may suggest you’re displaying the data in a suboptimal way. For example, there is no default for a numeric shape scale, because there’s no obvious way to map continuous values to discrete shapes.
Examples

```r
p <- mtcars
  ggvis(x = ~wt, y = ~mpg, fill = ~factor(cyl), stroke = ~hp)
  layer_points()

p %>% scale_numeric("x")
p %>% scale_numeric("stroke")
p %>% scale_nominal("fill")

# You can also supply additional arguments or override the defaults
p %>% scale_numeric("x", trans = "log")
p %>% scale_numeric("stroke", range = c("red", "blue"))
```

scale_datetime

A date-time scale controls the mapping of date and time variables to visual properties.

Usage

```r
scale_datetime(vis, property, domain = NULL, range = NULL, reverse = NULL,
  round = NULL, utc = NULL, clamp = NULL, nice = NULL, expand = NULL,
  name = property, label = NULL, override = NULL)
```

Arguments

- `vis`: A ggvis object.
- `property`: The name of a property, such as "x", "y", "fill", "stroke", etc.
- `domain`: The domain of the scale, representing the set of data values. For ordinal scales, a character vector; for quantitative scales, a numeric vector of length two. Either value (but not both) may be NA, in which case `domainMin` or `domainMax` is set. For dynamic scales, this can also be a reactive which returns the appropriate type of vector.
- `range`: The range of the scale, representing the set of visual values. For numeric values, the range can take the form of a two-element array with minimum and maximum values. For ordinal data, the range may be an array of desired output values, which are mapped to elements in the specified domain. The following range literals are also available: "width", "height", "shapes", "category10", "category20".
- `reverse`: If true, flips the scale range.
- `round`: If true, rounds numeric output values to integers. This can be helpful for snapping to the pixel grid.
- `utc`: if TRUE, uses UTC times. Default is FALSE.
clamp

If TRUE, values that exceed the data domain are clamped to either the minimum or maximum range value. Default is FALSE.

nice

If specified, modifies the scale domain to use a more human-friendly value range. Should be a string indicating the desired time interval; legal values are "second", "minute", "hour", "day", "week", "month", or "year".

expand

A multiplier for how much the scale should be expanded beyond the domain of the data. For example, if the data goes from 10 to 110, and expand is 0.05, then the resulting domain of the scale is 5 to 115. Set to 0 and use nice=FALSE if you want exact control over the domain.

name

Name of the scale, such as "x", "y", "fill", etc. Can also be an arbitrary name like "foo".

label

Label for the scale. Used for axis or legend titles.

override

Should the domain specified by this ggvis_scale object override other ggvis_scale objects for the same scale? Useful when domain is manually specified. For example, by default, the domain of the scale will contain the range of the data, but when this is TRUE, the specified domain will override, and the domain can be smaller than the range of the data. If FALSE, the domain will not behave this way. If left NULL, then it will be treated as TRUE whenever domain is non-NULL.

See Also

scales, scale_numeric, https://github.com/trifacta/vega/wiki/Scales#time-scale-properties

Other scales: scale_logical, scale_nominal, scale_ordinal; scale_numeric

Examples

```r
set.seed(2934)
dat <- data.frame(
  time = as.Date("2013-07-01") + 1:100,
  value = seq(1, 10, length.out = 100) + rnorm(100)
)
p <- dat %>% ggvis(~time, ~value) %>% layer_points()

# Start and end on month boundaries
p %>% scale_datetime("x", nice = "month")

dist <- data.frame(times = as.POSIXct("2013-07-01", tz = "GMT") +
  rnorm(100) * 60 * 60 * 24 * 7)
p <- dist %>% ggvis(x = ~times) %>% layer_histograms()
p

# Start and end on month boundaries
p %>% scale_datetime("x", nice = "month")
p %>% scale_datetime("x", utc = TRUE)
```
scale_numeric

Add a numeric scale to a ggvis object.

Description

A numeric (quantitative) scale controls the mapping of continuous variables to visual properties.

Usage

scale_numeric(vis, property, domain = NULL, range = NULL, reverse = NULL,
round = NULL, trans = NULL, clamp = NULL, exponent = NULL,
nice = NULL, zero = NULL, expand = NULL, name = property,
label = NULL, override = NULL)

Arguments

vis
A ggvis object.

property
The name of a visual property, such as "x", "y", "fill", "stroke". Note both
x and x2 use the "x" scale (similarly for y and y2). fillOpacity, opacity and
strokeOpacity use the "opacity" scale.

domain
The domain of the scale, representing the set of data values. For ordinal scales,
a character vector; for quantitative scales, a numeric vector of length two. Either
value (but not both) may be NA, in which case domainMin or domainMax is set.
For dynamic scales, this can also be a reactive which returns the appropriate
type of vector.

range
The range of the scale, representing the set of visual values. For numeric values,
the range can take the form of a two-element array with minimum and max-
imum values. For ordinal data, the range may by an array of desired output
values, which are mapped to elements in the specified domain. The following
range literals are also available: "width", "height", "shapes", "category10", "cat-
egory20".

reverse
If true, flips the scale range.

round
If true, rounds numeric output values to integers. This can be helpful for snap-
ing to the pixel grid.

trans
A scale transformation: one of "linear", "log", "pow", "sqrt", "quantile", "quan-
tize", "threshold". Default is "linear".

clamp
If TRUE, values that exceed the data domain are clamped to either the minimum
or maximum range value. Default is FALSE.

exponent
Sets the exponent of the scale transformation. For pow transform only.

nice
If TRUE, modifies the scale domain to use a more human-friendly number range
(e.g., 7 instead of 6.96). Default is FALSE.

zero
If TRUE, ensures that a zero baseline value is included in the scale domain. This
option is ignored for non-quantitative scales. Default is FALSE.
scale_numeric

**expand**
A multiplier for how much the scale should be expanded beyond the domain of the data. For example, if the data goes from 10 to 110, and expand is 0.05, then the resulting domain of the scale is 5 to 115. Set to 0 and use nice=FALSE if you want exact control over the domain. If left NULL, behavior will depend on the scale type. For positional scales (x and y), expand will default to 0.05. For other scales, it will default to 0.

**name**
Name of the scale, such as "x", "y", "fill", etc. Can also be an arbitrary name like "foo".

**label**
Label for the scale. Used for axis or legend titles.

**override**
Should the domain specified by this ggvis_scale object override other ggvis_scale objects for the same scale? Useful when domain is manually specified. For example, by default, the domain of the scale will contain the range of the data, but when this is TRUE, the specified domain will override, and the domain can be smaller than the range of the data. If FALSE, the domain will not behave this way. If left NULL, then it will be treated as TRUE whenever domain is non-NULL.

**Details**
The default values for most of the arguments is NULL. When the plot is created, these NULL values will be replaced with default values, as indicated below.

**See Also**
- scales, scale_ordinal, https://github.com/trifacta/vega/wiki/Scales#quantitative-scale-properties
- Other scales: scale_datetime, scale_logical, scale_nominal, scale_ordinal

**Examples**

```r
p <- mtcars %>% ggvis(~wt, ~mpg, fill = ~hp) %>% layer_points()
p %>% scale_numeric("y")
p %>% scale_numeric("y", trans = "pow", exponent = 0.5)
p %>% scale_numeric("y", trans = "log")

# Can control other properties other than x and y
p %>% scale_numeric("fill", domain = c(0, 120), clamp = TRUE)

# Set range of data from 0 to 3
p %>% scale_numeric("x", domain = c(0, 3), clamp = TRUE, expand = 0, nice = FALSE)

# Lower bound is set to lower limit of data, upper bound set to 3.
p %>% scale_numeric("x", domain = c(NA, 3), clamp = TRUE, nice = FALSE)
```
Add a ordinal, nominal, or logical scale to a ggvis object.

Description

Ordinal, nominal, and logical scales are all categorical, and are treated similarly by ggvis.

Usage

```r
scale_ordinal(vis, property, domain = NULL, range = NULL, reverse = NULL,
round = NULL, points = NULL, padding = NULL, sort = NULL,
name = property, label = NULL, override = NULL)

scale_nominal(vis, property, domain = NULL, range = NULL, reverse = NULL,
round = NULL, points = NULL, padding = NULL, sort = NULL,
name = property, label = NULL, override = NULL)

scale_logical(vis, property, domain = NULL, range = NULL, reverse = NULL,
round = NULL, points = NULL, padding = NULL, sort = NULL,
name = property, label = NULL, override = NULL)
```

Arguments

- `vis` A ggvis object.
- `property` The name of a property, such as "x", "y", "fill", "stroke", etc.
- `domain` The domain of the scale, representing the set of data values. For ordinal scales, a character vector; for quantitative scales, a numeric vector of length two. Either value (but not both) may be NA, in which case `domainMin` or `domainMax` is set. For dynamic scales, this can also be a reactive which returns the appropriate type of vector.
- `range` The range of the scale, representing the set of visual values. For numeric values, the range can take the form of a two-element array with minimum and maximum values. For ordinal data, the range may by an array of desired output values, which are mapped to elements in the specified domain. The following range literals are also available: "width", "height", "shapes", "category10", "category20".
- `reverse` If true, flips the scale range.
- `round` If true, rounds numeric output values to integers. This can be helpful for snapping to the pixel grid.
- `points` If TRUE (default), distributes the ordinal values over a quantitative range at uniformly spaced points. The spacing of the points can be adjusted using the `padding` property. If FALSE, the ordinal scale will construct evenly-spaced bands, rather than points. Note that if any mark is added with a `band()` prop, then the scale for that prop will automatically have `points` set to FALSE.
Applies spacing among ordinal elements in the scale range. The actual effect depends on how the scale is configured. If the points parameter is true, the padding value is interpreted as a multiple of the spacing between points. A reasonable value is 1.0, such that the first and last point will be offset from the minimum and maximum value by half the distance between points. Otherwise, padding is typically in the range [0, 1] and corresponds to the fraction of space in the range interval to allocate to padding. A value of 0.5 means that the range band width will be equal to the padding width. For positional (x and y) scales, the default padding is 0.1. For other scales, the default padding is 0.5.

If TRUE, the values in the scale domain will be sorted according to their natural order. Default is FALSE.

Name of the scale, such as "x", "y", "fill", etc. Can also be an arbitrary name like "foo".

Label for the scale. Used for axis or legend titles.

Should the domain specified by this ggvis_scale object override other ggvis_scale objects for the same scale? Useful when domain is manually specified. For example, by default, the domain of the scale will contain the range of the data, but when this is TRUE, the specified domain will override, and the domain can be smaller than the range of the data. If FALSE, the domain will not behave this way. If left NULL, then it will be treated as TRUE whenever domain is non-NULL.

See Also

Other scales: scale_datetime; scale_numeric

Examples

```r
p <- PlantGrowth %>% ggvis(~group, ~weight) %>% layer_points()

p %>% scale_nominal("x", padding = 0)
p %>% scale_nominal("x", padding = 1)

p %>% scale_nominal("x", reverse = TRUE)

p <- ToothGrowth %>% group_by(supp) %>%
  ggvis(~len, fill = ~supp) %>%
  layer_histograms(width = 4, stack = TRUE)

# Control range of fill scale
p %>% scale_nominal("fill", range = c("pink", "lightblue"))

# There's no default range when the data is categorical but the output range # is continuous, as in the case of opacity. In these cases, you can # manually specify the range for the scale.
mtcars %>% ggvis(x = ~wt, y = ~mpg, opacity = ~factor(cyl)) %>%
  layer_points() %>%
  scale_nominal("opacity", range = c(0.2, 1))
```
set_options

Set options for a ggvis plot

Description

Set options for a ggvis plot

Usage

set_options(vis, width = NULL, height = NULL, keep_aspect = NULL,
resizable = NULL, padding = NULL, duration = NULL, renderer = NULL,
hover_duration = NULL)

Arguments

vis Visualisation to modify
width, height Width and height of plot, in pixels. Default is 600x400.
keep_aspect Should the aspect ratio be preserved? The default value is FALSE, or the value of getOption("ggvis.keep_aspect"), if it is set.
resizable If TRUE, allow the user to resize the plot. The default value is TRUE, or the value of getOption("ggvis.resizable"), if it is set.
padding A padding object specifying padding on the top, right, left, and bottom. See padding.
duration Duration of transitions, in milliseconds.
renderer The renderer to use in the browser. Can be "canvas" or "svg" (the default).
hover_duration The amount of time for hover transitions, in milliseconds.

See Also

ggetOption and options, for getting and setting global options.
default_options to see the default options.

Examples

mtcars %>%
ggvis(~wt, ~mpg) %>%
layers()
set_options(width = 300, height = 200, padding = padding(10, 10, 10, 10))

# Display the default options
str(default_options())
set_scale_label

Set the label for a scale

Description
Set the label for a scale

Usage
set_scale_label(vis, scale, label)

Arguments
vis A ggvis object.
scale The name of a scale, like "x".
label Text to use for the label.

shiny-ggvis
Connect a ggvis graphic to a shiny app.

Description
Embedding ggvis in a shiny app is easy. You need to make a place for it in your ui.r with ggvisOutput, and tell your server.r where to draw it with bind_shiny. It's easiest to learn by example: there are many shiny apps in demo/apps/ that you can learn from.

Usage
bind_shiny(vis, plot_id, controls_id = NULL, ..., 
           session = shiny::getDefaultReactiveDomain())
bind_shiny_ui(vis, controls_id, session = shiny::getDefaultReactiveDomain())
ggvisOutput(plot_id = rand_id("plot_id"))

Arguments
vis A ggvis object, or a reactive expression that returns a ggvis object.
plot_id unique identifier to use for the div containing the ggvis plot.
controls_id Unique identifier for controls div.
... Other arguments passed to as.vega.
session A Shiny session object.
**Client-side**

In your UI, use `ggvisOutput()` in `ui.r` to insert an html placeholder for the plot.

If you’re going to be using interactive controls generated by ggvis, use `renderUI()` to add a placeholder. By convention, if the id of plot placeholder is called "plot", call the controls placeholder "plot_ui".

**Server-side**

When you run ggvis plot interactively, it is automatically plotted because it triggers the default print method. In shiny apps, you need to explicitly render the plot to a specific placeholder with `bind_shiny`:

```
p %>% bind_shiny("plot")
```

If the plot has controls, and you’ve reserved space for them in the UI, supply the name of the placeholder as the third argument:

```
p %>% bind_shiny("plot", "plot_ui")
```

**Examples**

```
## Run these examples only in interactive R sessions
if (interactive()) {

  # Simplest possible app:
  library(shiny)
  runApp(list(
    ui = bootstrapPage(
      ggvisOutput("p"),
      uiOutput("p_ui")
    ),
    server = function(..., session) {
      mtcars %>%
        ggvis(~wt, ~mpg) %>%
        layer_points() %>%
        layer_smooths(span = input_slider(0, 1)) %>%
        bind_shiny("p", "p_ui")
    }
  ))
}
```

---

**show_spec**  
*Print out the vega plot specification*

**Description**

Print out the vega plot specification
**show_tooltip**

*Usage*

```r
show_spec(vis, pieces = NULL)
```

*Arguments*

- **vis**: Visualisation to print
- **pieces**: Optional, a character or numeric vector used to pull out selected pieces of the spec

*Examples*

```r
base <- mtcars %>% ggvis(~mpg, ~wt) %>% layer_points()
based %>% show_spec()
based %>% show_spec("scales")
```

---

**show_tooltip**

Send a message to the client to show or hide a tooltip

*Description*

Send a message to the client to show or hide a tooltip

*Usage*

```r
show_tooltip(session, l = 0, t = 0, html = "")
```

hide_tooltip(session)

*Arguments*

- **session**: A Shiny session object.
- **l**: Pixel location of left edge of tooltip (relative to page)
- **t**: Pixel location of top edge of tooltip (relative to page)
- **html**: HTML to display in the tooltip box.
**sidebarBottomPage**  
*Create a page with a sidebar*

**Description**
This creates a page with a sidebar, where the sidebar moves to the bottom when the width goes below a particular value.

**Usage**
```
sidebarBottomPage(sideBarPanel, mainPanel, shiny_headers = TRUE)
sidebarBottomPanel(...)
mainTopPanel(...)
```

**Arguments**
- `sidebarPanel`  The `sidebarBottomPanel` containing input controls.
- `mainPanel`  The `mainTopPanel` containing the main content.
- `shiny_headers`  Should Shiny headers be embedded in the page? This should be TRUE for interactive/dynamic pages, FALSE for static pages.
- `...`  Additional tags.

**Examples**
```
sidebarBottomPage(sidebarBottomPanel(), mainTopPanel())
```

---

**singular**  
*singular*

**Description**
Use singular when you want constant x or y position.

**Usage**
```
singular()
```

```
scale_singular(vis, property, name = property, label = name, points = TRUE, domain = NULL, override = NULL)
```

vector_type

Arguments

vis A ggvis object.

property The name of a property, such as "x", "y", "fill", "stroke", etc.

name Name of the scale, such as "x", "y", "fill", etc. Can also be an arbitrary name like "foo".

label Label for the scale. Used for axis or legend titles.

points If TRUE (default), distributes the ordinal values over a quantitative range at uniformly spaced points. The spacing of the points can be adjusted using the padding property. If FALSE, the ordinal scale will construct evenly-spaced bands, rather than points. Note that if any mark is added with a band() prop, then the scale for that prop will automatically have points set to FALSE.

domain The domain of the scale, representing the set of data values. For ordinal scales, a character vector; for quantitative scales, a numeric vector of length two. Either value (but not both) may be NA, in which case domainMin or domainMax is set. For dynamic scales, this can also be a reactive which returns the appropriate type of vector.

override Should the domain specified by this ggvis_scale object override other ggvis_scale objects for the same scale? Useful when domain is manually specified. For example, by default, the domain of the scale will contain the range of the data, but when this is TRUE, the specified domain will override, and the domain can be smaller than the range of the data. If FALSE, the domain will not behave this way. If left NULL, then it will be treated as TRUE whenever domain is non-NULL.

Examples

mtcars %>% ggvis(~mpg) %>%
layer_points() %>%
scale_nominal("x") %>%
add_axis("x", title = "", tick_size_major = 0)

# OR
mtcars %>% ggvis(~mpg) %>%
layer_points() %>%
scale_singular("x")

# OR, even simpler
mtcars %>% ggvis(singular(), ~mpg) %>% layer_points()

# In the other direction:
mtcars %>% ggvis(~mpg, singular()) %>% layer_points()
Description

The `vector_type` collapses down the class of base vectors into something useful more for visualisation, yielding one of "datetime", "numeric", "ordinal", "nominal" or "logical".

Usage

\texttt{vector_type(x)}

Arguments

\texttt{x} a vector

See Also

`default_scale`, which uses this when picking the default scale.

\begin{center}
\textbf{vega_data_parser} \hspace{1cm} \textit{Determine the vega data type for a vector}
\end{center}

Description

This is used to specify the data type so that the appropriate parser is used when Vega receives the data.

Usage

\texttt{vega_data_parser(x)}

Arguments

\texttt{x} A vector.

\begin{center}
\textbf{waggle} \hspace{1cm} \textit{Waggle back and forth between two numbers}
\end{center}

Description

Waggle back and forth between two numbers

Usage

\texttt{waggle(min, max, value = (min + max)/2, step = (max - min)/50, fps = 10)}
Arguments

- **min**: A minimum value.
- **max**: A maximum value.
- **value**: Starting value. Defaults to half-way between min and max.
- **step**: How much value changes at each frame. Defaults to 50 steps between min and max so it takes 5 seconds to waggle once.
- **fps**: number of frames per second.

Examples

```r
span <- waggle(0.2, 1)
mtcars %>% ggvis(~mpg, ~wt) %>%
layer_points() %>
layer_smooths(span = span)
```

---

**zero_range**

_Determine if range of vector is close to zero, with a specified tolerance_

**Description**

The machine epsilon is the difference between 1.0 and the next number that can be represented by the machine. By default, this function uses epsilon * 100 as the tolerance. First it scales the values so that they have a mean of 1, and then it checks if the difference between them is larger than the tolerance.

**Usage**

```r
zero_range(x, tol = .Machine$double.eps * 100)
```

**Arguments**

- **x**: numeric range: vector of length 2
- **tol**: A value specifying the tolerance. Defaults to .Machine$double.eps * 100.

**Value**

logical TRUE if the relative difference of the endpoints of the range are not distinguishable from 0.

**Examples**

```r
eps <- .Machine$double.eps
zero_range(c(1, 1 + eps))  # TRUE
zero_range(c(1, 1 + 99 * eps))  # TRUE
zero_range(c(1, 1 + 101 * eps))  # FALSE - Crossed the tol threshold
zero_range(c(1, 1 + 2 * eps), tol = eps)  # FALSE - Changed tol

# Scaling up or down all the values has no effect since the values
```
# are rescaled to 1 before checking against tol
zero_range(100000 * c(1, 1 + eps))  # TRUE
zero_range(100000 * c(1, 1 + 200 * eps))  # FALSE
zero_range(.00001 * c(1, 1 + eps))  # TRUE
zero_range(.00001 * c(1, 1 + 200 * eps))  # FALSE

# NA values
zero_range(c(1, NA))  # NA
zero_range(c(1, NaN))  # NA

# Infinite values
zero_range(c(1, Inf))  # FALSE
zero_range(c(-Inf, Inf))  # FALSE
zero_range(c(Inf, Inf))  # TRUE

---

**Pipe graphics**

**Description**

Like dplyr, ggvis also uses the pipe function, `%%` to turn function composition into a series of imperative statements.

**Arguments**

- `lhs, rhs` A visualisation and a function to apply to it

**Examples**

# Instead of
layer_points(ggvis(mtcars, ~mpg, ~wt))
# you can write
mtcars %% ggvis(~mpg, ~wt) %% layer_points()
